SIR,—The fleet-surgeons of the navy on the active list will read with regret the following official notice, as it deprives them of one of the coveted appointments due to them after years of expatriation in varied climates, and of confinement within ships—an appointment previously held by a naval surgeon on the retired list:—

"Admiralty, 22nd June.—The Lords Commissioners of the Admiralty have this day appointed John H. Aldridge, Esq., M.D., to be Visiting Surgeon at Southampton for the purposes of the Contagious Diseases Acts, 1866 to 1869, *vice* Acheson, deceased, and have nominated Dr. Simon Halford Hobley to act for Dr. Aldridge in the absence of that gentleman."—(*The Times*, 26th June, 1880.)

The junior members of the medical profession will be prompted to carefully examine, if it should ever be published, the report of the recent Admiralty Committee, presided over by Admiral Hoskins, C.B., for an explanation of the causes that have conspired to render the Naval Medical Service unpopular at the medical schools! If this report is deficient, or has ignored this important detail, the profession is in duty bound to ask that a Royal Commission may give a full and searching inquiry into the mismanagement of the Naval Medical Service that has brought it into its abject state. It is to be feared that the same spirit of intolerance still reigns and rules over naval surgeons as held sway in the first decade of the present century, when jealousy was so strikingly shown after the battle of Trafalgar.

It may be reasonably asked what have been the claims of the medical Directors-General of the Navy to their long terms of office? How has the Naval Medical Service been treated in comparison with the combatant branch of the navy and of the Army Medical Department since 1805? Why is it that the literary merits and labours of naval surgeons have been shelved in the non-publication of the *Blane Gold Medal* journals, the property of the nation, but withheld contrary to the intentions of its founder from public reading and open criticism?

Medical students can draw their own conclusions, and may form this as their final opinion, that the Government does persistently all that lies in its power to render the Naval Medical Service unattractive and inferior to that of the army.

With thanks for your valuable efforts,

I remain, Sir, yours truly,

July, 1880.

RODERICK RANDOM.

To the Editor of THE LANCET.

SIR,—As I take an interest in the Naval Medical Service, could you inform me what is the cause of the delay in issuing the Warrant for its improvement? I understand that the Committee appointed to inquire into its unsatisfactory state have long since finished their sittings. Is it expected that there will be seventy candidates for the Naval Medical Service at the next examination on August 9th (for such is the number of vacancies now), and that the medical schools will send forth men who will prefer a sea service, with far inferior pay, compulsory loss of time on half-pay, and a lower retirement, to a land service? Is it expected that the hope of good things coming may induce some to offer themselves even independent of those who fail to enter the Medical Department of the Army?

A dilatoriness in issuing the Warrant, and letting the profession know what are its provisions, is hardly the way to induce good men to enter the service.

I remain, Sir, yours truly,

July, 1880.

ENQUIRER.

Senega.—Niemeyer's Medicine (2 vols.); Flint's Physiology and Henman's Physiology; Garrod's *Materia Medica*; Ringer's Therapeutics; Sibson's Medical Anatomy; Bryant's Surgery; Klein's Handbook for the Physiological Laboratory; Squire's Pharmacopoeia.

Enquirer.—Cassell's.

"NEW INSTRUMENT FOR CLEFT-PALATE."

To the Editor of THE LANCET.

SIR,—Seeing an article in THE LANCET of July 24th on an instrument brought out by Dr. Edward Woakes, we beg to contradict the following statement:—"The principle of the shuttle now introduced for the first time as a surgical appliance"; having made a somewhat similar instrument, with shuttle action, for a Dr. Furlong, of Enniscorthy, Ireland, more than three years ago. We would not have taken any notice of the matter, but think we would not be doing justice to Dr. Furlong (the inventor of the shuttle action cleft-palate instrument) by overlooking the statement.

Yours truly,

Dublin, July 26th, 1880.

O'NEILL, SON, AND THOMPSON.

TREATMENT OF OPIUM-EATING.

SURGEON T. MAYNE, Narsingpur, in a communication to the *Indian Medical Gazette*, reiterates his belief that the best method of treating opium-eating is to stop the supply at once. He refers to sixteen cases which had been under his care, one of which was a patient exceedingly weak and emaciated, and the results tend to confirm Mr. Mayne in his opinion. The condition of the patient, he states, begins to improve perceptibly about a fortnight after the withdrawal of the opium.

AN ANCIENT MEDICAL CHARITY.

To the Editor of THE LANCET.

SIR,—On the boundary line of Rochester and Chatham is situated the Chapel of St. Bartholomew, together with the ruins of the Hospital for Lepers, which was attached to it. These formed one institution, founded by Gundulph in 1078. The Lepers' home is replaced by our excellent General Hospital, and we are endeavouring to restore the venerable Norman Chapel, now over 800 years old, the sole remaining link which binds us to what is, I believe, the oldest medical charity in England. Plans were furnished by the late Sir Gilbert Scott, who speaks of the Chapel as a "precious archaeological and historical relic, the preservation of which is of the utmost importance." The sum of £600 is still required to complete this good work. Will you allow me to appeal to your readers for help on medical, ecclesiastical, archaeological, and architectural grounds? I will gladly furnish the fullest particulars to anyone who may be disposed to assist, and I hope that some of those whom God has prospered in their profession may be willing to give of their substance for the preservation of His House.

I remain, Sir, yours truly,

JOHN BAILEY,

Chaplain of the Chapel and Hospital of St. Bartholomew, Rochester.

August, 1880.

Dr. F. Fourniss-Brice.—We agree with the view taken by the surgeon of the ship. Medical men travelling as passengers on board ships have no right to interfere, and are committing a flagrant breach of professional etiquette in interfering, with the duly qualified and appointed medical officer in charge.

Army Doctor.—1. The Secretary of State for War.—2. £350 per annum.

R. B.—We can only say that the gentleman named is a registered practitioner.

THE LATE DR. JOHN MACDONALD.

To the Editor of THE LANCET.

SIR,—May I be permitted to say that your article on the late Dr. John Macdonald has given universal satisfaction in Buenos Ayres; but, in doing justice to our lamented friend's merits, you have, on one point, done an unconscious wrong to others of the profession. I refer to the following paragraph:—"Three medical men only remained—one only, Dr. Macdonald, remained till all was over—in a plague-stricken city of some 150,000 inhabitants."

I know that medical men of other nationalities braved the whole plague, though their names I cannot for the moment call to mind; but, from my own circle of acquaintance, I can supply those of at any rate two more Englishmen, to whose devotion during the pestilence you will not, I trust, grudge a similar tribute of respect. They were Dr. Valentine Conyngham (since dead) and Dr. Charles Bailey Greenfield.

I enclose my card, and beg to remain, Sir, yours obediently,

Buenos Ayres, April 20th, 1880.

J. G. X.

BLINDNESS IN CONNEXION WITH PREGNANCY.

To the Editor of THE LANCET.

SIR,—Seeing in your issue of June 12th an account of a case of Blindness in connexion with Pregnancy, by Dr. Thompson, of Leamington, the following may prove interesting to many of your readers:—

On Feb. 28th, 1880, I was summoned to attend Mrs. C—, who was in the last month of pregnancy. At 11 A.M. she was seized with severe headache and dimness of sight. On my arrival at 2 P.M., I found her totally blind, with widely dilated pupils and unconscious. At 4 P.M. she had a severe convulsion, followed by four more in rapid succession. At 5.30 P.M., the os uteri being patulous and dilatable, I delivered her by version of a fully-developed, though small, female child. Convulsions, though less severe, continued until 7 A.M. the following morning. On my visit at 8 A.M. she was still unconscious and perfectly blind. On March 1st she had regained consciousness and partial vision, and had had no recurrence of convulsions. From this date she gradually recovered her sight, and was at the end of a fortnight downstairs, perfectly well.

I am, Sir, yours faithfully,

J. BEDFORD KERSWILL, M.R.C.P. Ed.

St. Germans, Cornwall, July 6th, 1880.

"LEGALISED QUACKERY AND LOW CHARGES."

To the Editor of THE LANCET.

SIR,—As a comment on your article headed as above, I would ask you to compare the payments made by the, so to say, legalised dispensaries to their medical men. For example, you published some time back the sums received yearly by the medical officers to the Reading Dispensary. If you calculate the number of visits paid at home and the patients seen at the dispensary, you will find that, allowing sixpence for each visit at their homes, it will leave threepence halfpenny for each prescription and examination of the patients attending at the dispensary; yet the medical men who submit to such payments are praised, while their poorer brethren are chastised.

I am, Sir, yours &c.,

August, 1880.

H. F. S.

Ignoramus.—We presume the husband could exert legal pressure in such circumstances in various ways. The question is legal rather than medical. We should be glad to hear further of the case.

THE Editor of the *New Zealand Herald* is thanked for his just vindication of the profession.

F.R.C.S. 80.—We do not reply to questions unaccompanied with the name of the inquirer.

Hinc Sanitas has omitted to send his name.

PERAMBULATORS.

To the Editor of THE LANCET.

SIR,—Mr. Punch is fond of pointing out the dangers to which perambulators subject the limbs of the general public. I would ask you to call attention to the perils to which these machines in their present make expose the tender offspring of the public.

My attention has been drawn to this subject by the difficulty I have had in finding suitable machines for my patients and friends, and by the fact that when I wanted a coach-perambulator for one of my children suffering from spinal caries, I could not buy it, and had to have one made. There are in ordinary perambulators three great defects, the lesser of which I consider to be, insufficient support on each side of the child, so that he falls into a bad position if he is weak or is allowed to go to sleep. Next to this is the attachment of the handle to the body, the nurse's hold interfering with the swing of the carriage. But the main fault is that the springs are much too rigid; anyone may find out, by pressing heavily on the seat, that the machine is made to bear weight, and not to be elastic, and this fault is rendered more important by the smallness of the wheels; for a very slight knowledge of mathematics will show that the jerk a small wheel receives in passing over a stone or a roughness in a pavement is far greater than would be given to a larger wheel. The best kind of spring for perambulators is a helix of two or three turns. I first saw such on a rather costly little carriage at Coventry, and have since tried in vain to obtain them; but I believe that if perambulators were made with this valuable addition, they would not cost many shillings more than they do without it. Bicycle wheels with rubber tyres are an improvement, but, involving an extra outlay of a pound, are not likely to be very commonly used. I have found that one of the usual infant bone-shakers may be turned into an easy carriage by having a loose seat fitted, resting on two spiral couch-springs, its back being supported by shorter ones.

That this matter is really one of preventive medicine, and deserves the attention of the profession, is the humble opinion of,

Yours very truly,

C. P. COOMBS, M.D.

Castle Cary, July, 1880.

Presidential Address,

*Delivered at the Meeting of the British Medical Association,
at Cambridge, on August 10th, 1880.*

By G. M. HUMPHRY, M.D., F.R.C.S.,
SURGEON TO ADDENBROOKE'S HOSPITAL, CAMBRIDGE.

PROFESSOR HUMPHRY welcomed the Association to Cambridge, and bade the members realise that not only the learned living, but the many illustrious dead who had made every spot in that town sacred also, bade them welcome. As they recalled the names of many great men who had, by their work, adorned their profession and that University, the question, Why there was now so little connexion between the old universities and the medical profession? would certainly arise in their minds, and they would be asking, Why the study of medicine was almost entirely disregarded at the great seats of learning?

The question recurs, What has prevented its being so? Such barrenness in a great faculty was certainly never intended—was not contemplated—by our founders and first legislators. In the earliest college statutes, permission or direction is given to some of the members to pursue the study of medicine. In the scheme for the university, which was in the main taken from the University of Paris, the faculty of medicine was placed on a par with those of theology and law, and the provisions for teaching and graduating in the three faculties were alike. In the professorial foundations by Henry VIII., by which the professorial system, as distinguished from the preceding method of teaching by regents, bachelors, and doctors, was inaugurated, medicine shared in common with the other faculties. The Regius Professorship of Physic received at that time an endowment and a status similar to those of theology and law; and in the additions to the professoriate which were subsequently made from time to time, the medical sciences have had their fair share. Thus, instead of any idea of stifling them, we recognise a reasonable provision for their nurture; and among the hopeful visions of the early benefactors of Cambridge must have been the scion of medicine, which they grafted and tended, flourishing as a goodly tree, drawing sap from the best sources of science, spreading forth its branches, and bearing rich fruit to England.

How have these intentions been foiled? Whence the mildew which blighted the plant, and deprived so many ages of its produce?

To these great and interesting questions, as to many others on subjects no less largely affecting the welfare and destiny of man, the answers are not direct and easy, and are to be found, if at all, only by a careful study of the history of the past.

In the early part of the thirteenth century, when the gathering of pupils and teachers here seems first to have come under the legal direction of the sovereign, when students were arriving from Paris, and Cambridge was beginning to organise itself upon the model of that great university, the study of medicine, which meant little more than a culling of the views of Aristotle and Galen, obscured and misrepresented in their transmission through Arabian translations, was as much confined to Salerno¹ as law was to Bologna, and theology to Paris. Learning, though reviving from the depression which almost amounted to extinction, was at a low ebb, especially on the north of the Alps, and was chiefly in the hands of the clergy, who thought secular knowledge to be unworthy of the attention of men whose minds should be engrossed with the great subject of the, as they imagined then impending, dissolution of the universe; and natural science, where it had any existence, was still poisoned by the follies and mysteries of alchemy, which had not yet given way before the genius of Roger Bacon. This country which, five centuries earlier, before the desolating inroad of the Danes, had taken the lead in Europe, and had sent from its schools of York and

Canterbury men who, under the far-reaching wisdom of Charlemagne, drew the first outlines of the French and German universities, was now in the background—at any rate, it could boast of no superiority. Grammar—that is, Latin, and arithmetic and the logic of Aristotle, as handed down by the Arabians, and expounded by Thomas Aquinas and Duns Scotus, formed and remained for centuries the basis of education in arts. Astronomy and mathematics were but little studied. Some passed on to the faculties of theology and canon law; but very few, not more than one or two in a year, were attracted by that of medicine. Those who make any progress in it were compelled to resort to foreign universities, as did Caius and Harvey to Padua and Bologna, in which latter place Vesalius, after the long and almost unbroken interval² which had elapsed from the time of Galen, was venturing to dissect the human body, and was followed by Eustachius and Fallopius. Caius, Harvey, and others returned to England; but none of them came back to Cambridge to found a school of medicine here, or to add the lustre of their names, and the vigour of their intellect to such school as there was here, for there must have been some sort of medical teaching in the university. There were then, as there ever have been, greater pecuniary and courtly attractions elsewhere. They proceeded, on their return from abroad, to practise their profession, or prosecute their studies, in various parts of England. Caius, it is true, after practising in Shrewsbury and Norwich, was not unmindful of his college, which he refounded and governed till shortly before his death in 1573, though apparently he still resided chiefly in London. In his foundation he was not forgetful of the interests of medicine; and he showed his sense of the importance of anatomy, acquired doubtless during his residence with Vesalius at Padua, by obtaining, in the sixth year of Queen Elizabeth, a licence that his college might, for ever, yearly take the bodies of two malefactors and dissect them without the control of any person. Whether Harvey, when at Caius, may have derived from this any stimulus to his researches, or, indeed, whether the privilege was ever acted on, I cannot tell.³ But that there was no great accession to medical study and teaching in Cambridge we may infer from the fact that Glisson, who held the Regius Professorship of Physic for forty years, from 1637 to 1677, was a resident in London.

Ere this events had occurred which seriously influenced the relations of London, Oxford, and Cambridge to the study and science of medicine. The highly learned Linacre, the great promoter, indeed renovator of learning, more particularly of Greek, in this country, beholding with concern that the practice of medicine was chiefly engrossed by illiterate monks and empirics, endeavoured to strike at the root of this evil by obtaining from Henry VIII., in 1518, letters patent for the foundation of his College of Physicians, with the privilege of licensing practitioners throughout the kingdom. The graduates of Oxford and Cambridge were exempted, forasmuch as, by virtue of their degrees, they were independent of the College, except within its precincts.⁴ Linacre lived to carry out and superintend his plan. Lectures were delivered at the College, and London thus became a centre of teaching, as well as of licensing the practitioners of medicine and surgery; and a new and formidable rival to Oxford and Cambridge was raised in the growing capital of the kingdom. But Linacre, who had been a student and doctor of Oxford, and an incorporated graduate of Cambridge, was not unmindful of the two universities. He showed his anxiety for their welfare, and his desire to promote the study of medicine in them, by bequests for the foundation of lectureships. Unfortunately, owing to the mismanagement of his trustees, these intentions were never carried out. The proceeds of his property, assigned for the

² Mondini appears to have dissected two females in 1315, at Bologna, and wrote a work on anatomy, which for three centuries was the textbook in the Italian schools.

³ Caius lectured on anatomy at the College of Surgeons in London for twenty years. He appears to have introduced the study of practical human anatomy into England. If his intentions with regard to dissection in his College in Cambridge were really carried out, it is probable that human dissection in this country was first practised at that College; and Harvey may have there acquired an insight into the structure of the human body which led to the formation of his views respecting the circulation of the blood.

⁴ Shortly before this time it had, been enacted (not improbably through the advice of Linacre) by a statute—which seems to have been the earliest statute in this country for the regulation of medicine—that no person should exercise as a physician or surgeon unless examined and approved by the bishop of the diocese in which he lived, who called to his assistance expert persons in the faculty.

¹ Salerno probably owed its early distinction as a university to its lying on the high road of the Crusaders. Robert of Normandy stopped here, on his way home, to be cured of a wound.

purpose, were, in great measure, lost, and the residue was diverted by private influence, at Oxford, to Merton College, and, at Cambridge, to St. John's College. The result upon medicine of what Linacre effected in his life was perhaps greater than that accomplished by any other man in this country, and it might have been far greater had his wise and beneficent intentions been fulfilled. What he left to others to perform, however, missed its mark, and his desire to place in the university scale a gift that might balance the effect of his munificence in London was woefully frustrated.

The metropolitan influence grew fast. The great centre attracted the practitioners, the teachers, and the students of medicine; and to the universities was left little beyond the function of giving a preliminary training to the few who could avail themselves of it. It must be remembered that in no other country are there ancient and powerful competing corporations similar to our Colleges of Physicians and Surgeons, and having power to grant licences to practise. In other countries the universities are the only avenues, each in its particular division, to medicine, as well as to theology and law. This very important difference, which is too often overlooked, must ever be borne in mind in making comparisons between the English and the other European universities. Add to this the small population of the districts in which Oxford and Cambridge are situated, together with the proximity of an overshadowing metropolis, and the difficulties attendant on the development of medical schools in the universities are sufficiently apparent.

To proceed, however, with my brief narrative. During the seventeenth and eighteenth centuries, the influence of Aristotle gave way to that of Bacon and Newton, and the system of the university verged more and more to the exclusive pursuit of mathematics and natural philosophy; the method of written examination, which had previously been subordinated to the scholastic exercises, became organised, the valuable fellowships and scholarships were given in accordance with the result of them, the spirit of emulation was excited, and the preparation for the examinations, which had been originally instituted in Paris for the purpose of testing the ability of those who sought to teach, became the too absorbing pursuit; the teaching of the professors, as well, for the most part, as the subjects taught by them, was thrown into the shade, and the students were brought almost entirely under the influence of the college authorities and the private tutors. Classics, at length, contrived to force a recognition. The rich prizes given exclusively for these two school subjects extended the study of them into too late a period of life, attached an undue importance to them, dwarfed all other subjects, both at the schools and at the universities, deterred those students from coming to Cambridge who had not a taste or capacity for them, or who had not the sufficient means of prolonging their school education, and, to say nothing of the religious restrictions, had well nigh divested the university of the character of a national institution, and of its claim to public sympathy and regard.

Happily, the reform from within was at hand; and, thanks to the liberal thoughts and wise discernment of the leading minds of the last generation—more particularly of Whewell and Sedgwick, of Peacock and Henslow—the tide was at length turned. Slowly and somewhat tremblingly the advancing wave of broader educational view came on, and showed its first influence, in 1851, in the foundation of the natural and moral sciences triposes. These were followed in succession by the theological, the law, the historical, the Semitic, and the Indian languages triposes. The subjects of these triposes are growing in estimation and in favour; the provision for teaching them is, year by year, more carefully and liberally made; and rewards for the successful study of them are more willingly granted.

Why not a medical tripos also? I may suppose you inquiring. I can only answer by expressing the hope that, when you next come to Cambridge, you may be relieved from the necessity of asking the question.

At the same time that a wider range was given to the studies of the place, the rigid and inelastic statutes of Elizabeth, which had for three centuries held the university with an iron grip, have been relaxed under the heat of public opinion—that sterling friend to Cambridge—and have given way to a freer constitutional code, which has afforded scope to, and thrown into strong relief, the naturally liberal spirit of the place.

As a result, the university has been opened to all comers

from all parts of the world, of every rank and of every religious persuasion. All are on an equality. The College stamp is no longer necessary; for the non-collegiate student stands on the same level with the collegiate. He enjoys the advantage of not being distracted by the anxiety for college rewards, and he can regulate his expenses by the measure of his purse. The requisite tests of general education may now, and should, be passed before the student comes up to Cambridge, or in his first term of residence, so that the whole of the university period may be devoted to those branches of medicine or natural science which are selected. Time is thus economised, and the well-grounded student may pass into the profession through Cambridge almost as quickly and economically as by any other route. It can be no longer urged that the middle classes are excluded from Cambridge, or discouraged from coming; or that the medical student cannot reasonably look forward to obtain a degree. All may come to the waters and drink, not without money, but without any undue cost, not without price, but with the price of that labour and perseverance which will bring their own sure reward.

That a great future, most potent for good, in connexion with medicine, is open to Cambridge I cannot doubt. The opportunity is before her—not, I grant, to make amends for past shortcomings. That can never be done. The past can no more be made amends for than it can be recalled. The debt of lost time and occasion cannot be repaid, except in so far as regret for the omissions of the past may stimulate to better effort in the future. The opportunity is open, not simply to influence the few, but to leave the large masses of the profession. The opportunity lies in a progressive advance and expansion of the teaching, under which I include examining; for examining should ever be regarded as the handmaid and most important adjunct of teaching. In proportion as Cambridge avails herself of this opportunity, and in that proportion only, will her influence upon medicine be great and good. Her social advantages are much and rightly valued; her literary renown is high; her academic prestige is great; her buildings are inspiring; her history is long and noble; but it is not upon these, but upon the high character of her teaching, that her future must stand. No other foundations will carry the temple to which coming generations are to be attracted. This ought to be so, and it will be so. The ideal, the æsthetic, the poetic, the conventional "gentlemanly" may, and should, give their tone and refinement and play their parts in the formation and elevation of character. The *literæ humaniores* are the proper, the requisite, complement to the *ars et scientia medicinæ*; but the real basis of university success in medicine, as indeed in the other faculties, must be the soundness, and thoroughness, and high standard of its teaching. These will be the measure of the dimensions, and will give solidity to the building; those may impart tone and grace to its structure. Cambridge must give that kind of teaching which will engender broader and clearer appreciation of principles, which will render the study of medicine a medium for the cultivation of intellect, as well as a means of passing into a profession and earning a livelihood. It must show the scientific to be the natural and necessary adjunct to the practical, and must weave the two together into the woof of a high educational system. In no other branch of knowledge are the two so naturally and so entirely conjoined; in no other is there so much that is calculated to give strength and balance to the thinking and the observing faculties; none in which mental and bodily effort is more required and more telling. There is no one, therefore, which is more worthy of university culture, or which would more truly profit by it. May we not also say that, of all the physical sciences, medicine is the most difficult, the most important, the highest? What problems can be so hard of solution as those which relate to the aberrations of the most exquisite of organisms—the organism in which the properties of matter reach their maximum of variety, of complexity, of exquisiteness of combination and action—the organism in which they have their outcome in an association with the marvellous attributes of responsibility and intellectual process. These problems of healthy and morbid action transcend all known methods of calculation; and, as is too commonly found under such circumstances, are liable to fall under the range of demonology and quackery—at any rate, to come within the scope of that mysterious and unfathomable *ignotum* which transcends the *magnificum*. The very difficulty of the problems causes them to be ignored or overlooked.

Men scarcely venture, or are able, even from a distance, to contemplate them, and therefore have a tendency to leap over them on to conclusions, without calculating the data which brought them there. That these hard problems may, and will one day, be brought within the domain of exact science, and be seen to be regulated by clearly-defined law, we may well believe; and we may also believe that, to effect this, in many of the instances, will, through long ages, afford unceasing labour to the investigator, and test the highest powers of the thinker. Indeed, the little way we have been able to make along the path of true medical science in the centuries during which we have laboured at it is scarcely enough even to open to us the difficulties that lie along it; and we may well believe that many of the enigmas of the science, of those more especially which have relation to psychological abnormalities, must await their solution till the far off, possibly the latest, cycles of human thought and work.

The importance of the result in this, as in so many other things, is proportionate to the difficulty. When we contemplate the effect upon the physical and moral condition of the people which is likely to result from a clearer knowledge of physiology and pathology; of the causes, nature, and prevention of disease; of the influences of hereditary transmission of peculiarities of temperament; of the various circumstances attendant upon progressive civilisation and social changes; of atmospheric, magnetic, and climatic variations upon those nice balances of function, and those delicate modifications of them which constitute disease—when we contemplate, I say, the vast importance of all this in its bearing upon the physical, mental, and moral status of man, and when we remember that it is the special object and duty of medical science to investigate and elucidate all this, and to formulate principles and rules for our guidance as individuals and as legislators, we find ourselves ready to assent to the striking statement of Descartes, that all great movements in the world of thought, of philosophy, of morals, and of government, are to come out of medicine.

And is such a subject, so fitted to evoke and invigorate the mental powers, and upon the successful prosecution of which the future destiny and welfare of our nation and of our race so much depend, not to receive its fair recognition in this great seat of learning? Is Cambridge to stand aside for the future, as she has too much done in the past, and keep aloof from the task of generating and wielding this potent force? Is this important member of the body politic of the university to be suffered to go un nourished and untended, to the great detriment of the whole? My own experience tells me that such is by no means now, whatever it may have been, the feeling or desire of the members of the university. Certainly it cannot be the feeling or desire of the members of the British Medical Association. Your presence here is the expression of your sentiment, and will, I am sure, give the impulse you desire. You come, not as ordinary careless visitors, but as serious responsible men, who, for your brethren and children's sake, your profession's sake, and your country's sake, have a deep stake in this place. As such you are received. You come as representatives of the medical profession, as members—that is, of the great brotherhood of learning who ought to, and who must, exercise an influence upon all learning; as such you are hailed, and esteemed, and looked up to by the university.

It is in the preliminary subjects of medical study, those which form the subjects of the earlier medical examinations, in addition to the broad ground of general education, that Cambridge will find her most appropriate sphere. The feeling is growing that these subjects would, for many reasons, be best taught apart from the great centres of clinical instruction; and it would be an enormous benefit to the cause of medical education to secure a thoroughly good teaching in these subjects upon the basis of sound general education. This, I am sure, lies at the root of the improvement we are all desirous to effect in our profession; and it is in this work more especially that Cambridge may and ought to play an important and conspicuous part in the future.

In evidence of this, I may refer to the buildings—the New Museums—which will be occupied by you during the meeting, and in which a suspension of our ordinary teaching work is necessitated for the accommodation and carrying on of your Sections. And here I would observe, you must not suppose that “vacation” in Cambridge implies cessation of work. On the contrary, the practical classes are, for the

most part, continued during a considerable period of the vacation, and some of the best work of this kind is then carried on; because, the regular courses of lectures being discontinued, and the lecture-rooms yielding to the laboratories and the hospital, the student can devote his attention more uninterruptedly to them. This week's holiday is in compliment to, rather is enforced by, your presence. I make that remark because it is right you should know that the vacation is not now, whatever it may have been in times past, a vacant period in Cambridge; and because, unless you bear in mind that this week's interruption of medical study is an exceptional condition for which you are responsible, you would carry away a wrong impression of our vacation life. The erection of the buildings to which I have referred, with the laboratories, lecture-rooms, and dissecting-rooms, for experimental physics, botany, mineralogy, mechanism, optics, zoology, and comparative anatomy, and physiology, and the provision of a staff of professors and demonstrators, and the better provision for chemistry and human anatomy, are an evidence of the impulse which the teaching of these sciences has lately received in the university, and are the forerunners of further building upon the same plot, by which it is hoped that, ere long, geology will find a suitable dwelling, worthy of the name, and in honour of the memory of Sedgwick, and that a much-needed expansion of the chemical and medical schools will be effected. I speak of a much-needed expansion of the medical school—and those of you who are anxious to inform yourselves respecting this will have the opportunity of learning for yourselves that, though physiology is thoroughly equipped—as thoroughly as in any European school, and though the means of teaching and studying chemistry and anatomy have been augmented to meet the requirements of growing classes of students, yet in both of these a further improvement might with advantage be made. A well endowed professorship of pathology is about to be instituted, and a suitable pathological laboratory must be added. A fully complete curriculum Cambridge does not profess; but a sound scientific and practical teaching in the first two stages of medical education—in physics and chemistry; in anatomy and physiology, vegetable, comparative, and human—and a careful clinical training at the hospital, associated with pathology and therapeutics, are quite within our scope; and, I trust, will continue to be carried on with yearly increasing efficiency to a yearly increasing number of students.

ABSTRACT

OF THE

Address in Medicine,

*Delivered at the Meeting of the British Medical Association
on Aug. 11th, 1880,*

BY

JOHN BUCKLEY BRADBURY, M.D., F.R.C.P.,

PHYSICIAN TO ADDENBROOKE'S HOSPITAL, CAMBRIDGE; LINACRE LECTURER IN PHYSIC; MEDICAL LECTURER IN GONVILLE AND CAIUS COLLEGE; AND ASSESSOR TO THE REGIUS PROFESSOR OF PHYSIC IN THE UNIVERSITY OF CAMBRIDGE.

MODERN SCIENTIFIC MEDICINE.

In reviewing the progress in the science of medicine during the last ten years, every one must be struck with the influence which discoveries in physics and biology (especially physiology) have had upon it; and, in looking forward, it is impossible not to feel that further advances will largely depend upon discoveries in the physical and biological sciences—sciences which, I am proud to say, this university has of late done much to promote; and in which, by means of her physical, chemical, and biological laboratories, she endeavours thoroughly to train her medical students, as the only sure basis upon which their subsequent more purely medical studies can be built. The future progress of medicine depends, in no small measure, upon students thus scientifically educated and trained to exact methods of investigation. Physics and physiology are advancing the healing art each day, step by step, more nearly to the position of an accurate science.

It will be my endeavour, then, in this address, to show that medicine is something more than a practical art; and that the statement of the late Dr. Whewell, that "we have even yet no science of medicine," in the sense in which he used the term science—namely, "a collection of general truths inferred from facts by successive discoverers;" whatever truth there might have been in it when he wrote is becoming less and less applicable in the present day.

We can hardly estimate how much modern medicine owes to physics, unless we reflect how helpless the physician in the present day would be in the study of morbid processes and their results, and in the diagnosis and treatment of disease, without such instruments as the microscope, the thermometer, the ophthalmoscope, the laryngoscope, the aspirator, and other instruments in daily use. In the hands of skilled investigators these instruments of precision have worked changes in the diagnosis, interpretation, and treatment of disease of which the physician and surgeon of an older generation could never have dreamt.

I do not propose to place before you all the discoveries made by the aid of these instruments during the period alluded to. I shall content myself by referring to those only which appear to be of primary importance in marking the progress of modern scientific medicine.

MICROSCOPE.—By the aid of the microscope an advance has been made in the exact diagnosis of so-called idiopathic or progressive pernicious anæmia. This disease, although first described by Addison (probably in the *Medical Gazette* for March, 1849), has only during the last few years been generally recognised—about fifty cases have been recorded by various observers. So far as I can ascertain, Addison made no microscopic examination of the blood in this disease; but in the Guy's Hospital Reports for 1855, Dr. Wilks, who had been testing the blood in reference to the number of white corpuscles, soon after Bennett's and Virchow's discovery of leukaemia, thus alludes to it: "In that class of cases which had specially gained the attention of Dr. Addison, and which he has designated 'idiopathic anæmia,' and where, above all others, it might be presumed that the existence of an excess of colourless globules was possible, no such condition has been found.¹ This observation of Dr. Wilks has been confirmed by all subsequent writers on this disease, and, in addition to this means of diagnosis, other important microscopical changes have been noted in the blood in this disease, which help to differentiate it from chlorosis and other closely allied diseases, such as leukaemia, &c. Messrs. Mackern and Davy,² and other observers (especially Drs. Byrom Bramwell,³ Stephen Mackenzie,⁴ and Finny⁵), have noticed in blood, drawn from persons with this disease by the prick of a needle, that the red corpuscles do not collect into rouleaux, as in health, but lie separately, or form masses of irregular shape; that these corpuscles are very noticeably reduced in number, are variable in size, of great diversity in form, some being oval, others spindle-shaped, some having a tail-like projection, some are larger than the white corpuscles, others not one-fourth of the normal size. In all the abnormal corpuscles the so-called zoid or yellow substance (hæmoglobin) seems to be collected in one part, leaving the œcoid rest of the corpuscle (stroma) clear and transparent, and this probably gives rise to the apparent nucleation of the corpuscles.

I have carefully examined the blood in one well-marked case of idiopathic anæmia, and I failed to find the small spherical red corpuscles regarded by Eichorst as pathognomonic of this disease. Rosenstein, Grainger Stewart, and Bradford have also failed to find these "microcytes," and they have been seen by Cohnheim in a case of medullary leukaemia, by Dr. Litton in a case of phthisis, and by Dr. Greenfield in a case of Hodgkin's disease. Dr. Osler of Montreal has found similar corpuscles in his own blood, and in that of persons free from disease. These corpuscles cannot, therefore, be regarded as diagnostic of essential anæmia; but the three combined abnormal conditions—viz., diminution of the number of the red corpuscles, their paler colour, and the alteration of their shape and size—may be regarded as characteristic.

C. M. Sørensen of Copenhagen emphasises the counting of the red corpuscles for the purpose of exact diagnosis, and, from observations in eleven cases of this disease, says

that the number of red corpuscles counted (according to Malassez's method) is only one-fourth to one-twelfth of the normal number. Dr. Stephen Mackenzie has also made some valuable observations on the reduction of the red corpuscles, in various anæmic states; but in none did he find such a diminution as in this disease.

Whilst upon the subject of the microscopical examination of the blood, I must not fail to mention the ingenious hæmacytometer devised by Dr. Gowers, for estimating⁶ the corpuscular richness of any specimen of blood. This instrument has the great advantage of accuracy and simplicity of application in clinical practice, and is an improvement in the latter respect upon the "compte globule" of Malassez⁷ and the hæmatometer of MM. Hayem and Nachet. M. Malassez has also devised an instrument, the hæmachromometer, for estimating the amount of hæmoglobin in blood, which is both accurate scientifically, and most convenient clinically. He has pointed out that blood-corpuscle counting is of little diagnostic or clinical use unless combined with estimating at the same time the amount of hæmoglobin present.⁸

The diagnosis of idiopathic anæmia by means of the microscope furnishes us, then, with a "general truth" as to the abnormal conditions of the blood-corpuscles which has been "inferred from facts by successive discoverers;" and thus may serve to illustrate the statement that we have, at the present time, a true science of medicine in Whewell's sense of the word.

One further application of it as an instrument of precision is of considerable interest at the present time, and ought, perhaps, to be noticed in this address. It was only in 1860 that Zenker of Dresden made out, post-mortem, the disease of trichinosis in a patient who was supposed to have had typhoid fever. How many cases of trichinosis had before that been attributed to some other condition cannot be estimated. The microscope has discovered the disease, and by the aid of this instrument it will probably be stamped out. In the year 1876 there were in Prussia no fewer than twelve thousand inspectors charged with the duty of inspecting slaughtered swine. Trichinae were found in one of every two thousand animals. This is a humble use of the microscope, and one not entailing delicate manipulation and high magnifying powers. It is mainly to Professor Virchow, eminent no less as a practical administrator than as a scientific pathologist, that Prussia owes this great triumph of preventive medicine.

Mr. Power, one of the medical officers of the Local Government Board, was enabled, by microscopical examination of the muscles of the only fatal case of the outbreak which occurred on board the reformatory school-ship *Cornwall* in September and October of last year, to show the disease to be trichinosis, and not, as was at first supposed, enteric fever. It is highly probable that in future many cases of supposed enteric fever, for which no adequate cause can be discovered, will prove, as in the instance I have just quoted, to be due to eating trichinised meat.

A very remarkable fact in connexion with this investigation is the discovery by Mr. Power of bodies somewhat resembling trichinae in the voluntary muscles of two undoubted cases of enteric fever which had died in St. Thomas's and Greenwich Hospitals. Mr. Power offers at present no positive opinion as to the nature of these bodies, or their relation to enteric fever; but, if this disease should be found to be a form of trichinosis, our views as to its etiology and pathology must be very much modified.

THERMOMETER.—But the thermometer has done even more than the microscope to place medicine upon a scientific basis, and to refute the statement that "we have even yet no science of medicine." I think it may be said without exaggeration that the treatise on "Medical Thermometry" by Professor Wunderlich has more than any other work furthered the progress of medicine during the last ten years; for it is only during this period that the thermometer has come into general use in the profession, although the first edition of Wunderlich's book was published at Leipsic in 1868. This physician was enabled, from complete thermometric observations, extending over a period of sixteen years, in many thousand cases of disease, to abstract and formulate

well-founded general principles from the mass of separate cases; or, in other words, to form a collection of general truths inferred from carefully-recorded facts. Owing to his treatise, we have been able to diagnose diseases which at an early stage were previously confounded—e.g., acute tuberculosis and enteric fever. We have also become acquainted with the typical course which certain diseases run; and it is possible from thermometric observations alone to predict with almost absolute certainty the progress which many acute diseases are making. Probably no one phenomenon helps us so much as the temperature of a patient to reveal the existence of complications, and to predict the favourable or unfavourable issue of fevers and inflammations. Furthermore, as we have learned the natural course of most acute diseases, so have we come to trust less in drugs, and to leave more to nature, or, perhaps I should say, to careful nursing, rest, cleanliness, and suitable nourishment. Again, as the temperature can neither be feigned nor falsified, the thermometer may render us assistance in determining whether a disease is feigned or not.

In some diseases, such as acute rheumatism and enteric fever, the temperature indicates more truly the gravity of some cases than any other phenomena. Dr. Wilson Fox and others have shown that, by appropriate cooling of the body by baths and other external means, patients suffering from acute rheumatism, with a temperature of 110° Fahr., may be rescued from death. The method of cooling the body by affusion of cold or tepid water was known to Dr. Currie of Liverpool and other physicians at the end of the last century; but until the last few years this mode of reducing abnormal temperatures has never been systematically and scientifically carried out. In the German hospitals the method of treating the pyrexial state by the external application of cold has come into general use, and has also to some extent been introduced into private practice. Jürgensen, Liebermeister and Hagenbach, Ziemssen and Immermann, Brand of Stettin, and others, have published statistics of several thousand cases of fever treated in this way; from which it appears that the mortality has been reduced more than one-half, being now only from 3 to 10 per cent. In our own country, this method of treating enteric fever has not carried conviction to the minds of Sir W. Jenner⁹ and of Dr. Collie,¹⁰ Medical Officer to the Homerton Fever Hospital; but is well spoken of by Dr. Ord of St. Thomas's Hospital, and Dr. Cayley of the Middlesex and London Fever Hospitals. My own experience of this mode of treatment is limited to one case of enteric fever, in which the temperature reached 106° 8' Fahr., and which was successfully treated by baths.

The value of the thermometer in clinical medicine has recently received a fresh illustration in the most interesting researches of Peter and Vidal on local temperatures in acute pleurisy, phthisis, and some abdominal diseases. M. Peter has found in acute pleurisy, from a long series of investigations: (1) that the parietal temperature outside the pleurisy is from one-half to two degrees Cent. higher than the average temperature of the patient; (2) that the more rapid the effusion, the quicker the elevation of temperature; (3) that when secretion is not going on, and the level of the fluid remains stationary, the elevation of the parietal temperature decreases, but the temperature is still from one-half to one and a half degrees Cent. higher than the sound side; (4) that pleurisy not only raises the parietal temperature of the diseased side, but also that of the opposite side; but the parietal temperature of the diseased side is always higher than that of the healthy; (5) that, while spontaneous absorption of the effused fluid is going on, the parietal temperature drops gradually; (6) that in dry pleuritis the local excess of heat is less than when there is effusion, and the return to the normal temperature also occurs more rapidly; and (7) that the absolute elevation of the local temperature on the diseased side is more considerable than the absolute elevation of the axillary temperature.

M. Peter has also investigated the results of thoracentesis upon the parietal temperature, and has found, when the effusion is not reproduced, that although there is, immediately after the puncture, a slight rise, which lasts for some hours, nevertheless the parietal temperature afterwards decreases, and continues to do so until the normal figure is

reached, unless the effusion is reproduced, when the local temperature rises again.

The observations of M. Peter on local temperatures in pulmonary phthisis, which have been fully confirmed by M. Vidal, are even still more interesting. He believes that, as soon as tubercles occur at any point, the local temperature rises there, and he points out that in doubtful cases of phthisis, where the physical signs are not developed, this local thermometry may materially assist us in arriving at a correct diagnosis. M. Peter has made a further communication to the Académie de Médecine on the subject of local temperatures in abdominal diseases, and has indicated the differences between the local temperatures of the abdominal parietes in ascites and in the various forms of peritonitis. Local thermometry has also been applied to the detection of the precise locality of a cerebral lesion by Broca,¹¹ Dr. Carter Gray¹² of Brooklyn, and others. These temperature observations seem to be of value for the purpose of localising lesions. Dr. Gray has found, from observations on 102 males, among other things, that in health the temperature of the left side of the head is nearly one degree higher than that of the right, and that the average temperature of the frontal and parietal regions is nearly two degrees higher than that of the occipital. Lombard has also made elaborate experimental researches on the regional temperature of the head, but he is not "inclined to place much reliance on the examination of the relative temperatures of different parts of the integument of the head as a means of medical diagnosis." Dr. Gray, however, thinks the surface-temperatures at various points of the head indicate similar differences of temperature in the convolutions lying beneath those points. Cases have been recorded¹³ which, notwithstanding the adverse criticisms of Rendu,¹⁴ seem to show that we can attribute a positive value to local thermometry in making regional diagnosis in cerebral cases.

General thermometry has been found useful in diagnosing cerebral hæmorrhage from alcoholic poisoning, the general bodily temperature (rectal) falling at first below the normal in cerebral apoplexy, but not in drunkenness.

General thermometry also assists us in the differential diagnosis of true apoplexy from the so-called apoplectiform seizures, which occur in progressive general paralysis, disseminated sclerosis, cerebral softening, and also from uræmic coma. Charcot says, "I have demonstrated by repeated observations that in true apoplexy, especially when it depends upon cerebral hæmorrhage, the temperature constantly diminishes some moments after the attack, and afterwards remains, generally for at least twenty-four hours, below the normal standard, even when intense and reiterated convulsive fits occur"; whereas, in the congestive attacks (so-called apoplectiform seizures) which occur in progressive general paralysis and in disseminated sclerosis, "the temperature, on the contrary, rises above the physiological standard, and tends to become gradually more and more elevated, during the whole continuance of the attack."

In cases of cerebral softening, according to Bourneville, the "period of initial lowering" of temperature commonly met with in cerebral hæmorrhage is either absent or much less slightly marked; and, after the first two hours in a case of softening, the temperature may suddenly rise to 102° or even 104°, though it soon descends again to the normal standard, and afterwards exhibits altogether irregular oscillations (unless the pons Varolii be the part affected); whereas in cerebral hæmorrhage, it is found that, if the temperature after the "initial lowering" rises soon after the attack beyond 102° 5', it rarely sinks again to the normal standard, unless under the influence of a shock resulting from fresh hæmorrhage (Bastian). "In uræmic coma, according to Bourneville, the temperature of the body begins to fall at the onset of the seizure, and continues to sink as long as the coma persists, so that it may fall as low as 90° Fahr. in fatal cases. On the other hand, in coma due to cerebral hæmorrhage or softening, the lowering of the temperature is slighter in amount, and, in cases not fatal within this period, rarely lasts longer than twelve to twenty-four hours" (Bastian).¹⁵

The thermometer is also useful in forming a prognosis in these diseases, but into this I have not time to enter.

⁹ See THE LANCET, November, 1879, p. 715.

¹⁰ See British Medical Journal, Sept. 20th, 1879. Dr. Collie says those cases in which the bath is most useful are those in which, according to Liebermeister, it is contra-indicated—viz., "where there is a very high degree of heart-weakness."

OPHTHALMOSCOPE.—Physics have also furnished us with the ophthalmoscope, an instrument which, besides being invaluable in the recognition of diseases of the eye, has of late years assisted us materially in the diagnosis of intracranial tumours, syphilis, chronic Bright's disease, acute tuberculosis, tubercular meningitis, cerebral embolism, locomotor ataxy, and other diseases which need not here be specified.

Dr. John Ogle was the first physician in this country to introduce the ophthalmoscope into medical practice; and Dr. Clifford Allbutt's book, the "Ophthalmoscope in Nervous and Renal Diseases," has, as Dr. Hughlings Jackson well expresses it, "done more than any other work towards the integration of ophthalmology with general medicine." Dr. Gowers's "Manual of Ophthalmology" (Churchill, 1879) is an excellent representation of what is known on the subject up to the present time. In his address on "Ophthalmology in its relation to General Medicine," delivered before the Medical Society of London, Dr. Hughlings Jackson pointed out how frequently cases of supposed brain disease are indirect effects of anomalies of refraction, readily recognisable by the ophthalmoscope, and how the correction of a hypermetropia or a myopia by appropriate spectacles may completely remove these *quasi*-cerebral symptoms, and save patients from needless drugging with "nervine" and other medicines. These cases show so well the value of a knowledge of physics (optics), not only in the diagnosis of certain disorders, but also in their treatment, that I do not hesitate to quote a passage from the address on this subject:—"Mr. Brudenell Carter," Dr. Jackson says, "has reported a remarkable case of myopia, simulating brain disease, in the eighth volume of the Clinical Society's Transactions. This report should be carefully studied by physicians. The patient for supposed brain trouble took a voyage to Australia, but was no better for it. He was told that he must abandon the idea of carrying on the family business, or of taking any active part in life. This patient was immediately, thoroughly, and permanently cured by the adaptation of appropriate spectacles." Dr. Jackson also relates the case of a medical student who had attacks of vomiting and frontal headache brought on by reading, and on account of which he was obliged to give up work. After travelling abroad for two years, doing nothing towards his career, he fell under the observation of Mr. John Tweedy, and the nature of the affection being recognised, he was fitted with glasses suitable for the hypermetropic variety of astigmatism, and has been well ever since, and graduated at the London University.

The following case, which came under my observation in January, 1879, is one of no uncommon occurrence. A lady who had been ill for some time, and under two medical men, had occasion to consult an oculist for some defect of vision. The ophthalmoscope revealed retinal hæmorrhage, such as is met with in some forms of chronic Bright's disease. The urine was now for the first time tested, and found to contain a considerable quantity of albumen; but, previously to seeing the oculist, renal mischief had never been dreamt of. The lady died about eighteen months afterwards with well-marked uræmic symptoms.

Dr. Gowers¹⁶ relates a case in which the detection of an embolus in the central artery of the retina was the first thing which drew attention to the existence of the cardiac affection from which the patient suffered. The patient applied at the Moorfields Ophthalmic Hospital for a defect of vision, and then she was found to have mitral constriction.

The ophthalmoscope often enables us to detect inherited syphilis, when other indications, such as the peculiar teeth, are absent. The relation of disseminated choroiditis to syphilis is extremely striking and important; and such a distinguished observer as Hutchinson has gone so far as to say, that the patches of disorganisation left by choroiditis are almost as pathognomonic of inherited syphilis as the notched teeth.

Other interesting recent researches in this field of medicine are those of Dr. Gowers on the diminution of the calibre of the retinal arteries in some cases of Bright's disease with increased arterial tension; and those of Quincke, Becker, and Dr. Stephen Mackenzie on spontaneous visible pulsation of the retinal vessels in connexion with aortic regurgitation; and those of Mackenzie and others, on retinal hæmorrhages in connexion with purpura, leucocythæmia, idiopathic anæmia, ague, and diabetes.

Retinal hæmorrhages have also been observed in septiciæmia and pyæmia. In puerperal septiciæmia they almost

invariably occur during the last two or three days of life, according to Litten; and they augur an unfavourable termination of the case.

Another important condition, revealed to us by the ophthalmoscope, is the simple atrophy of the optic nerve—atrophy without precedent neuritis—which is seen in some cases of locomotor ataxy, and which may be of help in the recognition of this disease at an early stage. This simple optic atrophy can be sometimes seen before ataxy begins; and along with absence of the "tendon-reflex," or with the presence of the lightning-like pains, it is an almost certain indication that the disease has commenced.

The recognition of optic neuritis is also of great value both in the diagnosis and prognosis of intracranial tumours.

The ophthalmoscope must, therefore, no longer be regarded as an instrument of use only to the ophthalmic surgeon, but as a most valuable instrument in the detection of many morbid states which come under the notice of the physician.

LARYNGOSCOPE.—Our knowledge of the uses of the laryngoscope in clinical medicine to-day is little in advance of what it was ten years ago. Some new facts have, however, been added to our store of knowledge in this department of medicine.

Owing more especially to the careful observations of Dr. Marcet, we can detect tubercular disease in the larynx before there are any physical signs of its development in the lungs. When laryngeal phthisis is present there is a "whity, milky, probably purulent mucous fluid in the laryngeal cavity." The diagnosis of laryngeal phthisis is of more value in prognosis than is generally supposed, for if phthisis can be detected in the larynx we may be quite sure that the lungs either are, or will shortly become, tuberculous, if not obviously so at the time. It is also a well established fact that those cases of phthisis in which the larynx is early involved are less amenable to treatment than most other cases, and hence we are compelled to give a more gloomy prognosis.

We are also indebted to Dr. Marcet for pointing out the importance of examining the epiglottis with the laryngoscope. Cases of simple and syphilitic inflammation of this organ may be mistaken, as he has shown, for tubercular disease of the larynx, unless an examination is made with the laryngoscope.

In inflammation of the larynx, the laryngoscope helps us to ascertain the presence or absence of membrane, which the report on the subject of croup and diphtheria presented to the Royal Medical and Chirurgical Society by a committee, of which Dr. Dickinson was chairman, has shown to be of the highest importance, both as regards prognosis and treatment. Although the committee were unable to settle the vexed question as to what constitutes croup and what diphtheria, the evidence before the committee led them to the conclusion that most cases of membranous inflammation of the larynx were of a diphtheritic character.

SPHYGMOGRAPH.—In the field of medicine in which the sphygmograph has been used, the harvest has been more abundant than in the case of the laryngoscope, chiefly owing to the researches of Burdon Sanderson having been elaborated by Galabin, Mahomed, and others. In his thesis, read in 1873, for the degree of M.D. in this university, Dr. Galabin, formerly Fellow of Trinity College, corroborated the views of Burdon Sanderson, George Johnson, and others, on the use of this instrument in estimating the amount of arterial tension, as gauged by the height of the tidal or predicrotic wave of a pulse-tracing; and for the first time pointed out that high arterial tension exists in acute as well as in chronic Bright's disease. High blood-pressure gives the earliest indication of the grave series of degenerative changes throughout the body, known as chronic Bright's disease, and may, if neglected, lead to disastrous results both in disease of the arteries and of the heart. High blood-pressure is the cause of all so-called heart-disease in old persons; it is very amenable to treatment, and its treatment is imperatively necessary.

Dr. Handfield Jones¹⁷ has recorded a series of cases in which, without albuminuria or other symptoms of Bright's disease, the sphygmograph has sufficed to diagnose the disease, the high pressure in the pulse being really its pathognomonic symptom.

In a paper published in 1874,¹⁸ Dr. Mahomed tried to

¹⁷ Some Experiences of the Sphygmograph in Medicine, THE LANCET, 1876.

¹⁸ The Etiology of Bright's Disease and the Pre-albuminuric Stage, Transactions of the Royal Medical and Chirurgical Society.

show that a chronic condition of high blood-pressure led to arterio-capillary fibrosis. This view he has further elaborated in a paper in the last volume of the "Guy's Hospital Reports," where he says that the hard pulse—the pulse of high tension—is the sign of Bright's disease; and that it should altogether replace albuminuria, for this is only exceptionally present.

High blood-pressure gives rise to many functional as well as structural disorders. In the paper referred to, Dr. Mahomed described the occurrence of this condition in an acute and transient, as well as in a chronic and permanent, form, as the result of certain blood-poisons, and as an antecedent of kidney-disease. He has also demonstrated its existence in pregnancy, and thus indicated the connexion between pregnancy and kidney disease (so-called), and thus with puerperal eclampsia.

This condition of high blood-pressure appears to be recognisable early in life, before it has given rise to any structural changes, or symptoms, and may be described as depending on the *diathesis*, or less correctly on the *temperament* of the person.

Of the value of the sphygmograph in valvular disease of the heart, experience has shown that it is of use more as an aid to prognosis than to diagnosis; it enables us to gauge the extent of the lesion. It is also very valuable as a guide to treatment, and in watching the effect of treatment; also in estimating from time to time the advance or otherwise of the disease by comparison of tracings taken at different periods.

Dr. Mahomed has elaborated the use of the sphygmograph in the diagnosis of aneurism of the aorta; he has shown that it may in some cases be of value in determining the site of an aneurism, and in estimating the amount of arterial tension present, and the result of treatment upon it. The plan of treatment advocated in aneurism by Mr. Tufnell has for its object the reduction of arterial tension.

The sphygmograph is further valuable as a scientific means of watching the effects of drugs on the vascular system, especially with a view to their use in the treatment of Bright's disease and of aneurism, by reduction of arterial tension. Above all, it is valuable as an educator and interpreter to the finger.

The possibility of recognising Bright's disease in its pre-albuminuric stage by means of the sphygmograph leads me to think, with Dr. Handfield Jones, that this instrument has a great future before it. When people become wise enough to pay their doctors for keeping them in health by periodically examining them to see if there be any abnormal change taking place in their bodies, the sphygmograph must come into general use in our profession.

The remedies for high arterial tension generally are a reduction in the amount of nitrogenous food, purgatives, diaphoretics, bleeding, &c. A milk diet is of the greatest value in some of these cases, as Dr. George Johnson was the first to point out. I have over and over again relieved this condition of the circulatory system by placing patients in bed and on a milk diet. To show the value of bleeding in this condition I cannot do better than quote a case recorded by Dr. Alexander Harvey, Emeritus Professor of Materia Medica in the University of Aberdeen, in his work "First Lines of Therapeutics," of a young lad of eighteen, in whom general anasarca, accompanied by profound coma, occurred rapidly after scarlatina, and yielded at once to general blood-letting—the coma disappearing in ten minutes and the anasarca within twenty-four hours after the vascular tension had been relieved.

As the profession comes more and more to recognise the importance of increased blood-pressure the practice of bleeding must come again more and more into fashion. The *pulsus magnus, durus et tardus*, which the old practitioners invariably bled, was exactly the pulse of high pressure as we now recognise it. There can be no doubt that in the present day we too much neglect venesection. In cases of apoplexy, with increased vascular tension, bleeding is beneficial; and also in uræmic convulsions, which Mahomed regards as probably due to minute cerebral hæmorrhages, produced by increased arterial tension, and not to the circulation of excess of urea or ammonium carbonate in the blood (Frerichs), or to anæmia of the brain caused by spasm of the cerebral arteries (Hughlings Jackson and George Johnson).

Some time ago it was discovered that amyl nitrite and nitro-glycerine have the property of relaxing the arterioles,

and of thus temporarily reducing blood-pressure. This discovery affords a most beautiful instance of what I do not hesitate to call scientific therapeutics, and affords another example that medicine is advancing to the dignity of a science. The drugs I have mentioned are especially suited to those cases in which the heart fails to overcome the great arterial pressure, as, e.g., angina pectoris, and the angina attacks occurring towards the end of chronic Bright's disease. To Dr. Brunton we are indebted for the discovery of the action of amyl nitrite in angina pectoris. In his "Gulstonian Lectures," delivered in 1877, he cites a remarkable instance of its successful administration.

Nitro-glycerine has been shown by Dr. Murrell¹⁹ to have the same physiological action as amyl nitrite, and may be used in the same cases. Its effects are said to be more gradual and lasting; it may, therefore, be taken regularly three or four times a day, and the arteries thus be kept in a constant state of relaxation.

We have now seen how the sphygmograph has not only helped to point out the nature of pathological states, but also indicated the treatment suitable for them. There can be no doubt that this subject of arterial tension is one of the "burning" questions in medicine at the present time, and this must be my apology for having occupied so much time in placing it before you.

One other point of great importance, in reference to albuminuria and arterial tension, which must not be altogether passed over, is the so-called "Albuminuria of Adolescents," which was the subject of a paper by Dr. Moxon, in the "Guy's Hospital Reports for 1878." In these cases of albuminuria, which occur in young men from the age of sixteen to twenty-two, the albumen is not always present in the urine, but intermits; it is generally, however, present in the urine at some period of the day, most frequently in that passed after breakfast. These patients are usually languid, listless, complaining of headache, are anæmic, and "generally out of condition;" but after a variable time, under the influence of tonic treatment, the albuminuria usually entirely disappears, and the patient's health is restored. Now, in these cases of albuminuria, the arterial pressure is quite normal, or low rather than high. I have seen several cases of this description amongst the undergraduates of the university and others, and it is of the utmost importance to recognise them clinically, for the prognosis in them is favourable, and the line of treatment to be adopted the very opposite of that which obtains in cases of albuminuria with high arterial tension. I am disposed to agree with Sir William Gull, that the albuminuria in these cases is due to atony of vessels and nerves. He says that albuminuria occurs in young and growing men and boys almost as frequently as spermatorrhœa.²⁰

There can be no doubt that at the present time physicians do not regard simply the presence of albumen in the urine as so serious a sign as they would have done ten years ago. The late Dr. Murchison regarded some cases of albuminuria as due to hepatic derangement.

I would especially invite general practitioners in medicine to help us to solve the meaning of this intermittent appearance of an abnormal substance in one of the secretions. They have opportunities of watching cases in private from day to day, and of knowing the habits of their patients better than a physician, who is only consulted occasionally. It is of the utmost importance that the question should be settled as to whether these forms of albuminuria are due to removable causes, such as indigestion, &c., or whether, as Dr. Dickinson would have us believe, they represent the initial stages of granular degeneration of the kidney.

ASPIRATOR.—Another instrument of precision for which we are indebted to physics is the aspirator, which has proved such a great boon to the physician and surgeon in the diagnosis and treatment of various diseases, especially of hydatid disease of the liver. This disease is very prevalent in Cambridgeshire. During the eleven years I have been physician at Addenbrooke's Hospital I have treated a considerable number of cases of this disease with the aspirator, and only one has proved unsuccessful, and this by reason of the aspirator never reaching the sac, which had thick cartilaginous walls, although three punctures were made, and in all my cases, save the one just mentioned, the cure has, so far as can be ascertained, been permanent. I am not an advocate for making a permanent opening, unless suppuration has taken place, simply contenting myself with drawing

¹⁹ THE LANCET, 1879.

²⁰ Note to Dr. Moxon, Guy's Hospital Reports, 1878, p. 238.

off nearly, but not quite, all the fluid. My experience does not coincide with that of my friend, Dr. John Harley,²¹ who advocates a permanent opening, and the withdrawal of the hydatids from the cysts, and even of the parent cyst itself. This method was tried in some of my earlier cases, but was found to have no advantages over the simpler method, and occasionally some drawbacks, such as the setting up of a pleurisy or pneumonia, which nearly carried off the patients. Before using the aspirator in cases of suspected pleuritic effusion, hepatic abscess, &c., I now almost invariably make a preliminary exploratory examination with a large hypodermic syringe, which is really a sort of miniature aspirator. I was glad to see the importance of this preliminary test recently brought more prominently before the profession in a paper by Dr. Greenfield.²²

STETHOMETER.—The stethometer, invented by Dr. Ransome of Bowdon is another instrument of precision, of value in the detection of some chest affections. Like the sphygmograph, the stethometer is not of ready application at the bedside, and has consequently not come into general use in the profession. It is capable, however, of rendering important information in some doubtful cases of lung disease. According to Dr. Ransome, it has, in several instances, indicated traces of former lung disease that no physical examination of other kinds could display; hence it is certainly useful in examination for life assurance. Dr. Ransome, in a private note, informs me that he thinks stethometry of chief value in estimating the probable course of cases of phthisis and pleurisy. In the chapter on Prognosis in his book on "Stethometry," he spoke with diffidence on this point; but he is now much more certain of the value of exact measurements in this regard.

SPECTROSCOPE.—Another instrument which promises to be of use in clinical and pathological investigations is the spectroscope, which has yielded some important results in the hands of Dr. MacMunn.²³ By means of this instrument, it is said we can distinguish blood from the bladder or urethra from blood from the kidney, and blood from the stomach from blood from the lungs, &c.

ELECTRICITY.—The application of electricity to the diagnosis and treatment of diseases of the nervous system has been placed upon a much more scientific basis during the last decade. The researches, especially of Professor Erb of Heidelberg, on the quantitative and qualitative reactions of nerves and muscles to electrical currents, which are termed the "reactions of degenerations," are of the greatest interest and value in the diagnosis and prognosis of certain pathological states.

It is not contended for electricity that it alone is sufficient to enable us to diagnose any particular disease of the nervous system, but its reactions, when considered in conjunction with a careful consideration of a case in all its bearings, are often of valuable assistance in forming a correct view of it. Let me cite one or two examples in illustration of my meaning. A patient suffered, among other symptoms, from paralysis of the left leg. The reactions of the nerves and muscles to faradism and galvanism were normal. Now, in paralysis from brain disease, as a general rule, the electrical reactions of muscles and nerves are normal, which is not the case in paralysis from spinal disease or from disease of the nerves and muscles themselves. The case was diagnosed as depending upon cerebral mischief, and, at the necropsy, a tumour was discovered in the right hemisphere, in the posterior parietal region. Again, a patient has right facial paralysis. The response of the nerve to electricity is considerably diminished. This shows that the paralysis has not a central origin, but is due to cold; that the case is one of so-called rheumatic paralysis. The cases might be multiplied in which the diagnosis of a lesion respectively in the brain, spinal cord, or peripheral nerves, can be established by electrical tests.

Again, electricity is useful in helping us to diagnose diseases affecting the various structural elements which go to make up the spinal cord; but we must not place too much reliance upon it, as several of these elements may be affected at the same time, and we may have irritative as well as paralyzing lesions; and this constitutes the great difficulty in the science of electro-diagnosis. Even in some of these cases, however, electricity furnishes us with valuable negative evidence.

Electricity also assists us in distinguishing functional from organic paralyses, and is valuable in the diagnosis of paralysis from lead-poisoning.

The subject of electro-therapeutics is now assuming so much importance, and its proper application is one which involves so many technicalities, that I should hail with satisfaction the establishment of an electrical department, under the direction of a competent person, in connexion with the hospitals of this country, such department being for both paying and poor patients.

I have found electricity of considerable value in some cases of progressive muscular atrophy and of infantile paralysis; and there can be no doubt of its use in removing chronic facial paralysis from cold, and in some cases, of chronic neuralgia. Faradism and galvanism are the forms in which electricity is chiefly used in the present day; but static electricity, produced by the old plate-machine, has recently been found superior to these, in certain cases of hysteria recorded by Vigouroux, Dujardin-Beaumetz, and Erlenmeyer.

The treatment of aortic aneurism by galvano-puncture has met with some success in the hands of Dr. John Duncan, Dr. Simpson, of Manchester, Dr. McCall Anderson, of Glasgow, and others. I must confess I have never had the courage to try it, although I have had two or three cases under my care which might have been regarded as suitable for the operation.

METALLO- AND MAGNETO-THERAPY.—Connected with the subject of electro-therapy are the very interesting investigations of Charcot and others, on the influence of metals and magnets on the human body in cases of hemi-anæsthesia. The subject is not altogether novel, as it was a belief, even amongst the ancients, that metals applied to the body exercised some influence upon the nervous system.

Metallo-therapy has, however, entered upon a new phase since, in 1848, Dr. Burq propounded the two following propositions: first, "That in certain states of the nervous system, plates of metal placed upon the skin have the power of altering general and special sensation and cutaneous vascular supply, and that the susceptibility of individuals to the metals generally used—gold, silver, iron, copper, zinc—varies, a patient sensitive to one metal being insensitive to another; and, secondly, that when it has been ascertained to what metal the individual is susceptible, that metal may be successfully administered internally to cure the morbid state of the nervous system."

In 1876 the Société de Biologie appointed a committee, consisting of MM. Charcot, Luys, and Dumontpallier, to investigate the alleged phenomena, which presented its first report in April of the following year. The cases selected were chiefly those of hysterical hemi-anæsthesia, in which the patients had lost superficial and deep common sensibility, as tested by plunging long needles into the skin of parts usually most sensitive. The senses of taste and smell were usually abolished, and there was dimness of vision, with more or less colour-blindness. The skin was paler on the affected than on the sound side; the temperature also was lower, and the muscular power less. The results of the investigation bore out in every particular Dr. Burq's assertions. The application, for ten or fifteen minutes, of a metallic plate of gold, copper, or zinc—according to the susceptibility of a patient for a particular metal—to the anæsthetic part, restored for a time sensibility in the part. One of the most curious phenomena in connexion with these experiments is what has been called the "transference" of sensibility—that is, a loss of sensibility on the sound side in the parts symmetrically opposite to those in which it has been restored. In two cases of hemi-anæsthesia, dependent upon organic brain disease, the metals restored sensibility to the part affected, and the effect, instead of being transitory, as in hysterical hemi-anæsthesia, was permanent. The committee reported again, in 1878, on Dr. Burq's second proposition: "That the external metallic aptitude being known, the same metal administered internally will determine the same results as its external application." Five cases are recorded in which hysterical patients, sensitive to either gold or copper, recovered sensation on the internal administration of the chloride of gold and sodium, or of the binocide of copper. Very curiously, when the sensation had returned, the outward application of plates of gold or copper produced a relapse of the anæsthesia.

In a case of hysterical colour-blindness (achromatopsy), by the application of gold to the temples, the colours were restored in definite physiological order; and on the occurrence

²¹ See St. Thomas's Hospital Reports, new series, vol. viii.

²² THE LANCET, Nov. 1st, 1879.

²³ The Spectroscope in Medicine. By Charles A. MacMunn, B.A., M.D. 1880.

of a relapse, they were lost in the same order—a circumstance which excludes all suspicion of fraud.

Cases, similar to those reported by the French committee, have since been published by Drs. Anderson, Wilks, Inglis, A. Hughes Bennett, Professor Westphal of Berlin, and others, which leave little doubt as to the genuineness of the facts observed.

"Expectant attention" may explain much, but it does not explain all in these cases. "It cannot account," as the writer of the article on Metalloscopy, in the *Birmingham Medical Review* for April, 1879, justly observes, "for a patient recovering her perception of colours in exact correspondence with physiological law, as related in the second report of M. Charcot's committee. It cannot account for transference—a fact discovered by accident, to the surprise of the observers, and, we are told in one case, the horror of the patient. It cannot account for the positive and constant results of certain agencies and the negative results of others; the different effects of the different metals; of the two poles of the magnet; of the magnet with the circuit open or closed. Such facts as the permanence of anæsthesia, caused by superimposing another metal; the prevention of anæsthesia by the same means; the prevention of anæsthesia by placing another metal on the central side of the first, and the absolute powerlessness of the same metal, when placed on the distal side, are also quite opposed to the same views."

The practical outcome of these investigations is, in the hysterical cases, at present not very great. The restoration of sensation and also of motion by the magnet in some cases of organic origin (cerebral hæmorrhage, alcoholism, lead-poisoning) is, however, a great gain to practical medicine, and "transfer" is very rare in anæsthesia of organic origin.

Thus far, I have mainly endeavoured to show the advantages which have accrued to practical medicine from the use of instruments of precision, for which we are indebted to the science of physics; and perhaps I ought not to conclude without uttering a word of caution, especially to the younger amongst us, not to rely too exclusively upon the information derived from the use of these instruments, to which perhaps there is a great temptation. The knowledge with which they supply us is, on account of its accuracy, of the greatest value, and at present the advance in the recognition and treatment of disease is chiefly due to them; but we must not ignore the aids which stood our predecessors in such good stead—the information with which the physiognomy, especially of patients, furnishes us—the estimation of the nervous element in patients, and the other features of disease recognisable by our senses, which I need not here mention, but which are known to every cultivated physician, and which cannot be measured by any instruments. We must still, therefore, be contented *stare super antiquas vias*—cultivating that "tact" upon which our ancestors mainly relied.

Address in Surgery,

Delivered at the Meeting of the British Medical Association at Cambridge, Aug. 12th, 1880,

By TIMOTHY HOLMES, M.A., F.R.C.S. ENG.,

SURGEON AND LECTURER IN SURGERY AT ST. GEORGE'S HOSPITAL.

AFTER some introductory remarks on the relations of surgery as a science and art to the subjects of study which a university is intended to encourage, and observing that it would be a sorry day for our profession when it was thought to be falling backwards in the estimation of the "liberales" of the nation, the reader continued as follows:—

It would not, I think, be at all difficult to show that both the science and art of surgery have made as great progress in modern days as any of the purely physical sciences, or any of the arts which are the application of those sciences to matter. Last year the Association was favoured by the Orator in Medicine (Dr. Hudson of Dublin) with a *résumé* and criticism of the works of Laennec, so admirably lucid, so full of practical information, as well as of literary research, that it cannot but live in the memory of all who heard or read it. Let me try to give a similar, though of course a far weaker, tribute to the memory of one who has passed

from among us much more recently, who was a former President of this Association, and whose name can never be divorced from the history of the progress of surgery in these islands—I mean Sir William Fergusson.

It is not necessary for me to recall the particulars of the career of one whom most of us knew so well, or to give a catalogue of his works, or of the improvements which he introduced into practice. It will be enough for me to test the effect which his career has had on surgery by the result (as far as has been ascertained hitherto) of that portion of his teaching of which he was with reason the most proud, and which, as I contend, marks a great step in the progress of our art. I mean what Fergusson called Conservative Surgery—the excision of bones and joints. It is nothing to the point to say that Fergusson did not devise any of the operations of conservative surgery, that Park of Liverpool and White of London had excised the knee and the hips long before Fergusson's time, and that both operations had been repeated by other surgeons.¹ Those operations were practically disused. They could, hardly, indeed, have been expected to come into general use before the introduction of anæsthetics. But what Fergusson insisted on was something much beyond the substitution of one operation in surgery for another. It was the great principle of preserving a limb, and, as far as possible, the functions of the limb, whilst eradicating the disease of one of the joints—a principle as applicable to excisions as to amputations; and which, in the hands of later surgeons, will, I have no doubt, limit the use of many of the excisions as much as, when applied by him, it limited the use of amputation. For there is a vitality in all sound principles which not only outlasts the occasion that called them forth, but often renders the first form in which they appear speedily antiquated, and even apparently erroneous.

I am not sure that it will not be so with excisions in the lower limb, nor would it detract in the least degree from Fergusson's merit, in my mind, if it were so; nay, I think it would enhance it. What Fergusson contended for, and what many of his contemporaries were slow to admit, was that the surgeon should propose to himself not merely the cure of the disease, which often is easily within the reach of the amputating knife, but also, as much as possible, the restoration of the limb to its natural functions. That is common sense, you will say, and no discovery. To which I would reply that almost all great innovations in practice are really expressible in terms of the simplest common sense, and may be made to look like truisms; yet in the days I am speaking of, if I may trust my own recollection and a moderately extensive acquaintance with the surgical literature of the period, the principle of conservative surgery was anything but admitted. I can remember being present thirty years ago at the first excision of the knee which Fergusson performed at King's College Hospital, and I recollect the sort of half-anxious interest with which the novel proceeding was looked forward to, and the sort of half disappointment when it was found that the operation was nothing so striking after all—that it was simple, easy, bloodless, and quite within the reach of anyone who chose to repeat it. In those days who thought of laying open the cavity of a large joint—except, perhaps, as a desperate measure in cases of acute suppuration, in which amputation would have been extremely hazardous? Who ever thought of treating diseased joints by incision and drainage, or any of the milder forms of treatment which are now coming into common use? All this is now changed, I admit, as far as the surgery of the knee is concerned, and is perhaps in process of change in the case of the hip; but I am far from persuaded that it is when smaller parts are in question. I have seen many and many a foot amputated that I not only think, but (if such a term be applicable to a future event) *know*, might have been saved by some excision or partial removal of the tarsus. Yet if Fergusson's great principle, that two legs are better than one, be good in the case of the knee, surely the same principle, that ten toes are better than five, may be accepted in the case of the ankle or the tarsus. And the further application of the very same view of surgery is more and more coming into prominence—viz., that by judicious surgical interference more and more cases may be rescued from all mutilation whatever, and the limb be really conserved, unshortened, and in some cases even unstiffened, to bear its owner possibly through some future Peninsular campaign, "to go anywhere and do anything."

¹ See Mr. Jones's paper in the *Medico-Chirurgical Transactions*, vol. xxxvii., page 61.

"I know that it may be said that in this effort to reform the surgery of the joints—i.e., to eradicate incurable disease without removing the limb—Fergusson was not the first, or at any rate not alone. Nor was he.² It is extremely difficult at the present day—ὅτε πάντα δὲ δασταί, ἔχουσι τὴν παράτα ῥέχθαι—for anyone to strike out a path in which no shadow of a suggestion of priority can be claimed for any other wayfarer. So when Mr. Lister's theories of antiseptics and carbolic acid were first broached, who does not recollect how it was said, "Carbolic acid is nothing but phenol, and phenol has been used in France for years"? "Antisepsis is nothing but the prevention of unhealthy inflammation, and that has been the aim of surgery ever since surgery was practised systematically." Yet all this detracted nothing from the merit or originality of the proposal. So I have no doubt it is true enough that every surgeon who ever touched a "bad knee" would have been glad to cure his patient without amputation had he known how. I do not contest that in the excision of the shoulder and elbow Fergusson had models upon which he worked; but what I contend is that he erected all this into a system, and showed the profession what general aim to propose to themselves, and how to pursue it, and, further, that he reintroduced into practice two almost forgotten operations in lieu of amputation, or of the slow decay of chronic disease, which, however they may be superseded in many cases by yet more conservative methods, will always have their application in practical surgery; while the method itself will always be connected with the name of him whom it is my chief desire to celebrate—the great founder of conservative surgery.

Let me now invite your attention to a very humble attempt to estimate the precise value of the two operations so introduced into modern practice. And in making this attempt I shall altogether discard any effort after what is called "statistical accuracy." Surgical operations are steps—very important and decisive steps, it is true, but still only steps—in a surgical process which cannot be estimated unless much more is known about each case than so-called statistics (which in most cases are really only death-rates) can furnish.

It has seemed to me that nothing valuable can be got in this way; but it is a useful inquiry how far the alterations in practice which Fergusson introduced have kept their ground in his own and other large hospitals—i.e., as to excision of the knee; what evidence we have that it has replaced amputation of the thigh—how far it is used as a substitute for the expectant treatment—and what is its value in vicious ankylosis; and, as to excision of the hip, how far it has come into acceptance at all, and in what class of cases it seems useful.

It will be noticed that I confine myself to cases of disease. I have no personal experience of these excisions in traumatic cases, nor do I think that any adequate experience has as yet been acquired in civil practice. There can be no question that Fergusson's object in introducing the operation of excision of the knee was as a substitute for amputation, and he hoped, doubtless, to render amputation as superfluous in disease of the knee-joint as amputation of the arm is in diseases of the elbow.³ A very little experience, however, was quite sufficient to modify any such expectation, and to show that the operation is too dangerous even to come into use under some of the ordinary conditions of disease which are often successfully treated by amputation. I mean especially acute suppuration in the joint, advanced age of the patient, and concomitant constitutional affection. Surgeons were soon agreed that, if the operation were to be used at all as a substitute for amputation, it could only be in early life in chronic disease and in non-tubercular patients. This is equivalent to saying that the operation *per se* is more dangerous than amputation; and, although the fact was warmly contested when excision of the knee was in its infancy, I think no one contests it now. At first, indeed, the matter was argued more after the fashion of the advocate than that of the philosopher. A surgeon who said that excision of the knee is a wiser proceeding than amputation,

was represented as an "opponent of excision," and the controversy was carried on with sneers and insults, which are fit weapons enough in the *forum litigiosum*, but are surely out of place in an inquiry into the best method of curing disease. Happily, however, all this is a matter of the past. Some of us take a higher view of the utility of these operations than others, but few deny that both excision of the knee and of the hip have their place in surgery. All that remains is to ascertain as definitely as possible what that place is.

Now here we perceive a considerable change in the opinions of those surgeons who have practised excision of the knee ever since the introduction of the operation. When first introduced it was, as I have said, intended to supersede amputation in chronic disease; and it soon became clear that it could not do this, but at the same time it was seen that there is another very important aspect of the case—viz., how far excision ought to be used as a substitute for the natural one by ankylosis. You, Sir, have dwelt with unmistakable truth⁴ upon the frequent imperfections in the process of natural cure, and such imperfections must have presented themselves only too often to all of us. We must all have seen cases where, after years of suffering and enforced inactivity, the patient has obtained a reprieve, and has been able to use the limb for a time, then has followed another recrudescence of the disease, and, perhaps, the process has been more than once repeated. Ultimately, with a cumbersome, useless, painful limb, and possibly damaged health, he is glad to be quit of the offending joint, and would submit to amputation readily. In several such cases I have performed excision with great success, and I look on them as amongst the most appropriate for the operation. Hence occurs the question, How far is it justifiable to forestall all this suffering by a resort to excision in certain cases, even though the surgeon cannot say that the natural cure is in his judgment impossible, nor highly improbable? And there is a third class of cases, sometimes difficult to separate from those last mentioned, in which the ankylosis, though complete, is in such an unfavourable position that the limb is useless. Here, again, excision is, in my opinion, a most valuable operation; so that the question as to indications for excision of the knee has been enlarged since the reintroduction of the operation. We have no longer to resolve merely the question of the use of the operation as one of urgency in incurable disease—acute or semi-acute—but also its use as an operation of expediency in defective ankylosis, and in faulty or deformed ankylosis, and, still further, its use as a method of treatment—i.e., as a substitute for the expectant treatment.

Now, since the commencement of this controversy another and a most extensive change has come over surgical practice in the introduction of the so-called Antiseptic treatment. I must not enter on the wide field of discussion which the very name of this subject opens out. Let it suffice to say that on whatever other parts of it doubts exist in the minds of more or fewer of us, none, I think, deny that the excision and drainage of joints is more safe and more successful than we used to consider it,⁵ and that now many cases are brought to an apparently successful issue by means of this method of treatment which Fergusson would doubtless have excised, and which his followers continue to excise. I use the term "apparently successful" advisedly. In fact, in these cases in which the symptoms subside after incision and drainage, and the joint relapses into a quiet state with more or less of mobility, just as in cases of apparent cure by the expectant treatment, the question

² See the very modest statement which he himself makes of his claims in his second lecture on the Progress of Anatomy and Surgery, p. 34, &c.

³ If excision of the elbow has superseded amputation of the arm as a general practice for incurable disease of the elbow, why should not the practice hold equally good in the lower limb? That is a question which I for years put to myself; which I still do, though in a less uncertain mood; and it is a question which I avail myself of such an opportunity as this to put again to myself and the profession.—Lectures on the Progress of Anatomy and Surgery, p. 115.

⁴ When disease has proceeded to such an extent as seriously to alter or destroy the synovial cartilaginous or osseous structure of the joint, it is almost vain to expect that a useful joint can be restored—by which I mean a joint with useful movement, and able to bear the weight of the body well. Indeed, the limited movement which remains is commonly worse than useless: it is mischievous, by entailing weakness, with liability to return of disease, and permitting contraction to ensue. The best result that can take place in such a case is the complete abolition of the joint, with ankylosis of the bones. Even if the limb be bent or otherwise distorted, it is more likely to be useful when ankylosed than if movement continued. Unfortunately, as we know, this result does not very often take place at the knee. As the disease subsides, the articular surfaces become united; and that, perhaps, in parts only, by a soft fibrous medium, which permits some movement, and has little disposition to ossification, even under the long-continued favourable condition of perfect rest. In most of the limbs rendered crippled, useless, and wasted by disease of the knee, some movement of the joint remains—insufficient for any useful purpose, but enough to disable the limb from bearing weight.—(Humphry, On Excision of the Knee, Med. Chir. Trans., iii., 17.)

⁵ See an interesting paper by Mr. J. H. Morgan in the St. George's Hospital Reports, vol. ix., On the Opening and Drainage of Joints.

is, How far the apparent cure is sound and permanent? And it is a question which, for my own part, I am unable to resolve. I have a strong impression that those cases of ankylosis are the soundest which are the quickest and the most complete; and I am not sure that the retention of a certain imperfect movement in the joint is any real benefit to the patient. But on all these points we are totally deficient in any conclusive evidence. Hospitals can come and go, and little is known about them after they once disappear, but I must confess to a certain want of confidence in the permanency of the cure obtained by excision and drainage in a tolerably large proportion of the cases.

But though the treatment by excision and drainage is coming more and more into favour there are many hospitals at which it is untried, or, at any rate, is rarely adopted. So that, I think, we can fairly divide successes at the present day into two classes—viz., those who use excision of the knee chiefly or wholly as a substitute for amputation in certain selected classes of cases of incurable disease of the knee, and many of these use excision little, some hardly at all; and those who use it also as a substitute for the expectant treatment, and in this class are some who use incision far more freely than Fergusson ever did.

TABLE A.—Particulars and Results of Excision of the Knee at the undermentioned Hospitals, in the five years ending 1878.

Hospital.	No. of Cases.	Limits of age.	Result.			General Observations.
			Died.	Failed.	Succeeded.	
King's Coll.	21	7 to 32	2 from pyæmia and tetanus	2	18	The two cases in which the operation is said to have failed were, a total failure in which amputation was recommended, but refused; and one in which the patient was unable to walk without crutches. During the same period there were four cases in which either re-excision or some proceeding for straightening the limb or removing diseased bone was adopted, in all with apparent success.
St. Barthol.	24	2 under 5 years, 2 over 20 years	2, 1 pyæmia, and 1 not stated	7	15	
Guy's	89	Not given	6	10	73	No deaths out of 37 cases in the last two years of the period. The one death was after amputation.
St. George's	4	8 to 21	1	2, both amputated; 1 died	2	
St. Thomas's	62	Early childhood to 40	8	12	42	Of the 12 failures, 4 were amputated. I believe the 8 others are marked either as relieved or uncured.
Manchester	24	As above	1	8	15	All 8 unsuccessful cases amputated; one of these died; no other deaths.
Leeds	21	Do.	3	6	8	Four cases are unaccounted for. The 6 cases were all amputated, and, I believe, all recovered.
	245		23	47	173	Of the 47 failures, I believe 36 were amputated.

Appendix to TABLE A, showing the line of practice pursued at each of the hospitals named.

KING'S COLLEGE.—As a general rule, excisions of the knee are performed here in cases where the limb would otherwise have been amputated; but it is believed that some exceptions have been made to this rule—in cases where prolonged expectant treatment might have led to an ultimate cure of ankylosis. In the great majority of cases marked as successful, the soundness of the bony union after excision has been verified.

ST. BARTHOLOMEW'S.—The operation is sometimes (but rarely) performed as a substitute for amputation—more commonly in order to cut short the disease, which may be likely to last an indefinite time, and then to have a useless limb. It is very seldom resorted to in

acute disease immediately threatening the patient's life. It is regarded as a favourable operation in cases of vicious ankylosis. It is scarcely ever performed after the age of thirty-five.

GUY'S.—The operation is only practised by some members of the staff, and is used chiefly as an operation of expediency in cases which might possibly, after years of waiting, be brought to a more or less successful issue. Sometimes it is undertaken as an exploratory operation, to be followed afterwards by amputation if necessary. It is regarded as almost free from danger, all the cases being treated on the strict antiseptic system.

ST. GEORGE'S.—The operation has been, from accidental causes, very rarely practised during the time under review. It is used as a substitute for amputation in chronic affection of the bones, rather than as an operation of expediency.

MANCHESTER.—At this hospital the operation appears to be used chiefly as a substitute for the expectant treatment. The most favourable cases are those in which no suppurative exists, as in chronic rheumatic arthritis and in vicious ankylosis; next, degeneration of the synovial membrane; next, disease of the cartilages; then affections of the bone; and, least of all, those of disease of the bones, complicated with sinuses. Incision and drainage of joints has much limited the field for excision at this hospital, many cases being by such measures brought to useful ankylosis.

LEEDS.—Much the same observations apply to this hospital. Here also the incision and drainage of joints has been found very successful. Still, excision is freely resorted to in patients free from constitutional disease, young, and not so deeply affected as to necessitate the removal of the growing epiphyseal cartilages.

LIVERPOOL.—The operation seems rarely practised here, and is looked upon with little favour. Rest and extension, with incision and drainage if necessary, are believed able to cure such cases as are curable by excision.

DUBLIN.—The operation is not often practised in the hospitals of Dublin, and has never, as far as is known, been done in private. When used, it seems chiefly to be as a substitute for prolonged expectancy.

Now, how does this matter stand at our great schools of surgery? I propose here to give you a very short and succinct statement of the numbers of patients operated on by excision of the knee at given ages in the following hospitals: King's College, St. Bartholomew's, Guy's, St. George's, and St. Thomas's, Manchester, and Leeds. The ample experience of the Addenbrooke Hospital is contained in the volumes of the "Medico-Chirurgical Transactions," and in papers to which I now need not more than refer. I have also received general statements as to the practice pursued in Liverpool and Dublin, from surgeons of eminence in those cities, but no numerical lists. I shall not go into foreign practice. My impression is, that at Paris, and in France generally, the operation is little practised, from causes that I have already hinted at; and that in Germany, though more extensively employed, it is not a favourite, nor a very successful operation. Possibly things may change if the antiseptic system improves the safety of German hospitals for operative purposes in the future, as it has done in the past. But as yet I prefer to speak of hospitals where the surgeon can operate undeterred by the dread of those diseases commonly (but, as I think, most unjustly) called *hospital diseases*; and wherein, I believe, recovery occurs in about the same proportion of cases as in private houses. In America also the operation, if I have been correctly informed, is not in very common use.

Table A. may be taken as a fair specimen of English hospital practice; and it shows that the operation of excision is extensively used in all three classes of cases; but that the tendency of surgeons in late years has been more to bring the operation into use as one of expediency, or for the purpose of superseding the expectant treatment, than as one of urgency, or as a substitute for amputation. Yet you will observe the very gratifying impunity to life with which the operation has been performed in every one of these hospitals.

There seems no question that the mortality of all surgical operations has of late years greatly diminished. In amputation this has been the case to a very remarkable extent, as the writings of Mr. Callender and others show. The same appears the case also with excision of the knee. Mr. Bryant,⁶ writing in 1876, speaks of excisions as being "seven times as fatal as amputation in young life," meaning below the age of twenty; and says that the operation is too dangerous to be justifiable in childhood. Yet the remarkable fact is on record in the Guy's Hospital Reports, that during the five years ending 1878, eighty-nine excisions of the knee had been performed with only six deaths, and in the two last of these years, during which thirty-seven excisions had been performed, there were no deaths whatever. The explanation of the seeming discrepancy no doubt is, that Mr. Bryant's estimate of the mortality is taken from the experience of former years, while the list in question is formed in a great measure from the practice of one of the surgeons (Mr. Howse) following the antiseptic method in his treatment of the

wound.⁷ Almost equally good results, however, have been obtained without any antiseptic treatment by surgeons who are careful to dress their cases themselves, and to leave the parts long undisturbed. Thus my friend Mr. Gant informs me that of the twenty-five cases in which he has excised the knee, many of whom are adults, only two have died, and one of these deaths was from tetanus, an affection which has no known connexion with the method of dressing the wound. In none of these cases were any antiseptic precautions adopted either in the operation or after treatment. The patients were taken chiefly from the poor of the metropolis, and treated in one of the densest parts of the city in the Royal Free Hospital.

If this improvement in the mortality is found to be permanent it would extend the domain of excision, as against amputation, to the preservation of many limbs, and to the great benefit of the community. But if this is the case, concurrently must proceed another change, which with equal benefit to humanity will limit the application of excision in the one direction as much as it is extended in the other. I mean the change which will apply the method of incision and drainage, or incision and cauterisation, or incision and scooping, to many of the cases now claimed by excision.

In both directions—both where excision is pushed within the domain of amputation, and where milder and less radical measures are substituted for excision, the great idea of Fergusson is carried out—the preservation of the limb and its functions as far as is consistent with the eradication of the disease, which is what he meant by conservative surgery. Even when we set aside his work we are really only further honouring the master.

Speaking from my own experience of the operation, which I may say in passing is not small, I should say that in cases such as are usually reported strumous, where the bones are only superficially ulcerated, in cases of degeneration of the synovial membrane, in cases of limited inflammation tending to necrosis, in cases of abscess in the bone not extending too far from the joint, and in selected cases of rheumatoid arthritis, the operation may be tried in healthy subjects with fair prospect of success, and in childhood especially, without much detriment to the prospect of success in consecutive amputation, should that prove necessary. And as to the utility of the limb, when the process of union goes on rapidly, the limb is usually very strong, good, and useful, even if it be considerably shortened when the patient grows up.

Do not let us deceive ourselves in this matter. Since surgeons still seem to believe that the success of excision at its best is not much better than that of amputation. With no wish to speak disrespectfully of those who may in other departments of surgery have seen far more, and done far more than I have, I cannot but say that this opinion proves that they can have seen little of excision of the knee. It is said that individual successful cases prove little. This doctrine I utterly repudiate. They show precisely what we want shown—viz., what is the best that the operation has to promise if successful. I had the good luck the other day to see a man in whom nineteen years ago I excised the knee for very extensive disease, accompanied by imperfect ankylosis. He was then a child, and it was necessary to remove the whole of both epiphyses. The limb is now shortened seven inches; yet it is so serviceable that he had walked thirty miles in the day a few days before he saw me, without excessive fatigue.

But in what cases we ought to counsel our patients to incur the risk of excision is hard to define. I hope and believe that as the danger of other surgical operations is diminishing under improved methods of treatment, so is the danger of this also, and that the limit of age may be extended, and possibly the operation may be found applicable in future to more acute stages of disease than has been the case in the past.

It is the great length of time which is often required for the natural cure of these affections, when they have been allowed to reach a high degree, and the extreme uncertainty of the result when tested by the stringent conditions of manual labour or service of any kind, that causes the relative frequency of operations for diseased joints in hospital, as compared with private practice. But there is also another view of the matter. Allowing that ultimately, after a long period, ankylosis can be obtained, and the

joint disease be completely cured, is it at no expense to the general health that this has been done? Has the patient's expectation of life been in no respect damaged by months or perhaps years of confinement and inactivity? I think we are fairly entitled to argue that the patients would have had a better chance of reaching a ripe old age had a well-planned surgical operation restored them early to fresh air and the invigorating influences of active life and occupation. For all which reasons it seems to me that the timely excision of the knee is an operation well worth contemplating in cases where the natural cure drags on slowly.

Let me again beg you to observe that these observations apply to cases in which the disease has already reached an advanced stage. We see such cases only too often. A better and more rational system of treating such affections in their early stage would much diminish the proportion of grave maladies of the joints, and render both excision and amputation far more rare in hospital practice.

If this may be accepted as a fair summary of the most recent experience on the subject of excision of the knee, it might be expressed in the following propositions, which I submit to your judgment:—

1. Excision of the knee is one of the indispensable resources of surgery, and is useful in all three classes of cases—viz., in those where, otherwise, amputation would be included; in those where the expectant treatment might succeed, but is dubious, and in cases of vicious ankylosis.

2. As a substitute for amputation it is indicated in early life, and non-tuberculous subjects, in cases of limited caries of the bones, of degeneration of the synovial membrane, and under some conditions of necrosis of the articular surfaces, possibly also of abscess in the ends of the bones.

3. As a substitute for the expectant treatment, it seems to be justifiable, and is extensively used in cases where the patient's circumstances and the slow progress of the case render the surgeon hopeless or very doubtful of recovery with sound ankylosis.

4. It is also frequently used, and is very successful, in cases of vicious or deformed ankylosis.

5. Attempts have been made to limit the place of excision by opening the joint and drainage, and by some other partial methods. These attempts have been fairly successful, especially in cases where the affection is rather of the synovial membrane than of the bones, and they deserve more extensive trial than they seem as yet to have obtained.

6. At the same time the mortality from excision of the knee seems of late years to have been so greatly diminished that, as was fairly hoped, the limit of age which it has been found necessary hitherto to observe may be extended, and that it may be judged prudent to apply the operation to the treatment of the more chronic affections of later life, such as chronic rheumatic arthritis, more extensively than has been done up to the present time.

The figures (Table B) I have quoted show that excision of the hip is extensively practised and is fairly successful, although as to the precise amount of success obtained I fear our hospital records do not yield any trustworthy information, for the definite result of this excision is frequently not ascertained till a period at which the patient has passed out of observation. No doubt many of the cases entered as "recovered" had open sinuses, and were really uncured when the patients left the hospital.

In this excision, even more than in that of the knee, the question between operative treatment and the spontaneous cure is important, and is not very easy to settle. In this case also, even more than in that, the difference between hospital and private patients is conspicuous. Hip disease is anything but uncommon in the children of the wealthier classes. Yet excision of the hip, though not unknown, is very rare, and in the cases in which it is practised in private, it is probably more an operation of expediency than of urgency. Here again the question between the relative value of the cure by spontaneous ankylosis, and that obtained by excision is one of very great importance. My own opinion is strong, that the limb after excision, however successful, is very rarely indeed as useful as it is even after the average cure by ankylosis. Besides which, by appropriate surgical means, and especially by the careful maintenance of extension in the natural position of the limb, a cure can be in most cases obtained which is far superior to that which I have denominated "the average cure." If care is taken from the first to keep the head of the bone in the acetabulum, but not in painful contact with the surface of that cavity, and the limbs at the proper angle

⁷ In the Manchester Royal Infirmary also, where the antiseptic treatment is equally followed, there is only one death out of twenty-four operations.

with the pelvis, ankylosis can usually be obtained without any of that excessive shortening and malposition which are generally the termination of the natural cure.

TABLE B.—Particulars and Results of Excision of the Hip at the undermentioned Hospitals, in the five years ending 1878.

Hospital.	No. of Cases.	Limit of Age.	Result.			General Observations.
			Died.	Failed.	Successful.	
King's Coll.	16	4 to 40	3	5?	8	In 5, sinuses were still open when they left the hospital. The patients, as a rule, were much relieved by the operation. A patient aged 40 died; one aged 39 recovered. The information as to completeness of cure is defective.
St. Barthol.	6	5 to 20	1	—	5?	
Guy's	64	—	8	8	48	
St. George's	2	—	1	—	1	
St. Thomas's	76	1 over 50	17	34	25	Many of those classed as "failed" very probably ultimately recovered with useful limbs; but there is no distinct information. The patient aged 51 died.
Manchester	14	—	3	2	9	In the 2 classed as "failed" amputation was performed; in one successfully; the other is one of the 3 who died.
Leeds	37	1 age 48	8	8	21	The 8 cases of failure consist of 3 in whom amputation was performed, and 5 classed as "not improved." I believe the results in the 3 who suffered amputation are not noted. The patient aged 40 died.
	215	—	41	57	117	

Appendix to TABLE B.

KING'S COLLEGE.—All the operations here seem to have been performed for confirmed caries.

ST. BARTHOLOMEW'S.—This operation finds little favour as a rule, and is seldom resorted to as long as there appears a possibility of recovery by rest, &c. It is resorted to in cases of long-continued suppuration likely to end fatally.

GUY'S.—I am under the impression that in this hospital the cases of excision of the hip are chiefly in the practice of one or two of the surgeons, and that the operation is used at an earlier stage.

ST. GEORGE'S.—Here the operation is a very rare one, being reserved for cases obviously incurable otherwise.

ST. THOMAS'S.—Here, I believe, the operation is practised much more freely, and in earlier conditions of disease.

MANCHESTER.—Here, again, the operation seems to be regarded with little favour, and is used chiefly as a kind of adjunct to the natural cure—i. e., to afford a free opening, and remove great part of the diseased bone, even when the whole disease cannot be extirpated. Consequently the convalescence is very long. Incision and drainage of the joint is well thought of.

LEEDS.—At this hospital the operation has been tried in various ways; at one time, as a last resort, in cases where death was otherwise inevitable; again at an earlier stage of the disease; and again in contrast to other plans of treatment—i. e., expectancy, early excision, late excision, and amputation in advanced cases are being contrasted. Hitherto the experience of the operation has not been favourable.

LIVERPOOL.—The excision of the hip is very rarely practised.

DUBLIN.—In Dublin also the operation is little used. One surgeon—Dr. Barton—reports seven cases, with good results on the whole. Another professor—Bennett—is endeavouring to apply it to the cure of cases in the adult. It seems only employed in cases otherwise hopeless.

Some surgeons seem to think that it is a very common thing to find sequestra in the hip-joint, and I must allow that I have found them repeatedly in performing excision; but I think these were neglected cases, and that if due care be taken of the patient from the beginning of suppuration such extensive disease of the bone will rarely happen. I judge this from the experience of the Hospital for Hip Disease, where it is very rare for sequestra to be formed, or for the suppuration to go on unchecked till excision becomes necessary. It is in the experience of this hospital that we can read, in the plainest possible characters, what ought to be the treatment of disease of the hip-joint in childhood. The treatment pursued at our general hospitals usually fails, because the patient cannot be kept long enough under rest and constant supervision. Rest alone is not enough; a most careful attention to the position of the limb, vigilant watch

for any symptom of the formation of abscess, early opening of any collection which may have formed, and watchful management, are essential to cure; and all this may have to be carried on for many years.

Under what circumstances, then, does excision become necessary, and under what circumstances is it justifiable, though possibly not absolutely necessary?

Let me preface my answer to this question by giving you in a few words the experience of the hospital to which I have just referred; the only one, as far as I know, in this country where the ordinary disease of the hip in childhood is systematically treated from beginning to end. This institution receives cases of hip disease occurring in poor children, who have, therefore, been usually neglected, and in many of whom suppuration either exists or is imminent. Not a few are in an incurable condition when admitted, and it is this class almost exclusively that furnishes the fatal cases. No surgical operations are performed in the hospital beyond opening abscesses. The treatment consists in rest, with careful extension; and the most sedulous attention is given to see that the limb is brought into and kept in the natural position. When this has been effected by properly directed extension, and when all abscesses are in a perfectly quiescent state, the child is allowed to get up, wearing a Thomas's splint. No limit is fixed to the stay of a patient in the hospital, where children are often kept for several years.

Under this treatment the mortality of cases received in an early or curable condition is very small, though a good many of those received in an advanced stage of disease die, chiefly from amyloid degeneration and from tubercular meningitis. Not more than about 4 per cent. are transferred to the neighbouring Hospital for Sick Children for excision. In hardly any cases are sequestra seen to come away from the openings of the abscesses, and the resulting recoveries are with limbs which are straight, strong, and but little shortened, so that the patient can walk freely with the aid of a high boot, and in the best cases with little limping, limbs which contrast very remarkably with the results of excision. The patients are kept under observation for a long time after their discharge, so that the permanence of the recovery can be verified.

The question of the justifiability in the ordinary disease of childhood must depend in a great measure on the opportunities which the patient has of obtaining some such treatment as the above. Morbus coxarius is rarely incurable if taken early. I further believe that the constitutional mischief which so often ends the life of patients with advanced hip disease is usually not the cause, but the consequence, of that disease, and that if we would remove the cause by curing the disease early, there would rarely be any amyloid or tubercular degeneration of the viscera. If this be true, what follows? Why, that if we would or could treat hip disease early, before abscess has formed, by continuous and prolonged rest with extension, the great majority of the cases would recover without any abscess.

There are other and rarer conditions of the hip-joint, such as acute inflammation attacking the epiphyseal cartilage, which have been treated successfully by excision; and there are cases, though at present very few, in which the joint has been successfully excised at a later age for the cure of rheumatoid arthritis.

I would sum up what I have to say about excision of the hip in a very few words, by the simple statement that it ought to be very rarely indeed required, if the disease were treated properly at its commencement. In cases seen at an advanced stage of the disease, it is chiefly when sequestra exist that the operation is necessary, though it may be advisable as a means of shortening the treatment in other cases also, when the patient cannot obtain the prolonged surgical care which is essential to natural recovery.

I have thus tried to give you a general view of the results hitherto obtained from the great revolution initiated by Fergusson in the treatment of diseases of the joints of the lower limbs. The results have not been small, either in the point of view of operative surgery or in that of the preservation of limbs. Operations which used to be considered very fatal here, and which in some foreign countries were given up on account of their mortality, are performed in our hospitals with great success, and indeed are looked on by some surgeons as almost devoid of danger. Many limbs, which thirty years ago would most surely have been amputated, are now preserved in a very useful state; and the domain of conservative surgery has been pushed much further than Fergusson

had done, so that joints are frequently saved altogether which he would have excised. But, after all, much remains to be done. Just consider that I have produced a list showing that, at seven hospitals, two hundred and fifteen excisions of the hip and two hundred and twenty-five of the knee had been performed in five years; whilst probably the total number of such operations performed in private practice in the whole country during the period was less than a dozen; and yet every one would agree that the treatment of these diseases is far more successful in private than in public. What a comment is this on the boasts which we constantly hear of our hospital system, by which we are told that the poor get the same surgical skill for nothing which the rich purchase with large sums! The treatment of chronic diseases in the poor cannot be in any degree satisfactory till such diseases are treated at home; and that the most urgent question connected with our hospital system is how we can rid it of the incubus of the overgrown out-patient departments, which are no necessary part of the system, nor formed any part of it originally, but sprang up gradually as a substitute for the shamefully inefficient medical attendance then furnished to paupers. In order to this end, some efficient system of home attendance must be provided, and for this a scheme has lately been devised, which I hope will be discussed carefully and dispassionately by this Association. But whatever may be the fate of this particular scheme, the general result must be compassed in some way or other if the treatment of these affections is to be in any way really satisfactory.

I have spoken of some of the services which our eminent contemporary rendered to practical surgery and to the surgical professions. Time would fail me even to enumerate the rest, nor is it necessary. His presence has passed away from us too recently for them to have been forgotten even in this crowded time. One more remark may be allowed me. If we are now reaping the fruits of Fergusson's proposals to an extent which he himself hardly contemplated, it is because operations which, when he first ventured upon them, were extremely hazardous,⁸ are now found to be comparatively free from danger. I would claim a share in this happy revolution in practice for many unnamed workers in our hospitals and private practice, and I would remind my hearers that the mortality of surgical operations has been steadily diminishing in the practice of those who do not as well as those who do accept Mr. Lister's teachings. For my own part, I claim to be *nullius in verba magistri*, and I have freely criticised the facts and arguments adduced in favour of the germ theory and the antiseptic system. But let nothing that I have said be taken as implying that I am ignorant of the immense advance in practical surgery which that system has originated, or that I am unwilling to confess how great are the obligations of all surgeons to Fergusson's successor at King's College, Mr. Lister. It is not necessary to believe in all Mr. Lister's theoretical views, in order to admit that no one has had more splendid success in the great general object which he proposed to himself—the diminution of the mortality of surgical operations and injuries—and that no one has better deserved the abundant honours bestowed on him from every quarter, and now I am glad to see from this university also. When that great career has become a thing of the past, and some worthier orator shall discourse on the services which Mr. Lister has rendered to the world, he will be able to appreciate the value both of the theory and the practice. The time has not come, I think, to pass any judgment on the former; but I regard it as my duty, as I am sure it is my very great pleasure, to take every opportunity of saying that the practice which Mr. Lister has introduced has been eminently successful, and has been the chief cause of the great advance which operative surgery has made in recent years. It is the enviable privilege of King's College Hospital to have secured the services of two successive Professors of Clinical Surgery who have done more to advance that highest of all the developments of our art than any other men of this generation. Let us mingle with our reverence for the memory of the dead our gratitude and our best wishes for the living.

⁸ The mortality in Fergusson's hands was fifteen in forty down to the time when he delivered his Lectures on the Progress of Anatomy and Surgery (see p. 118 of that work).

THE Municipal Council of Paris has voted the sum of 1000 francs to the Medico-Psychological Society, for the erection of a statue to Pinel.

THE EPIDEMIC OF FEVER IN SWINEFORD UNION (COUNTY MAYO).

By C. J. NIXON, M.B., F.C.P., &c.,

PHYSICIAN TO THE MATER MISERICORDIE HOSPITAL, DUBLIN, AND
PHYSICIAN IN ORDINARY TO THE LORD LIEUTENANT.

THE Swineford Union, towards which so much attention has been recently directed, is situated at the north-east of Mayo, and is comprised chiefly within the baronies of Gallen and Costello. It is rather highly situated, has a population of about 54,000, an area of some 151,000 statute acres, and is divided into five dispensary districts—viz., Foxford, Kilkelly, Kiltamagh, Lowpark, and Swineford. The climate of Mayo generally, from which that of Swineford does not differ, is remarkably damp, rainy, and cold. This is due to its high mountains, large areas of bog, and its proximity to the sea. The rural districts of the union consist mainly of reclaimed moor or mountain, and wide plains of bog, thickly interspersed in parts with rocky islands. There is, however, nothing in the climate or in the soil which can be said to give rise to endemic disease, and the average death-rate of the union presents nothing exceptional, being as low as 14·8 per 1000 for the past ten years.

Within the limits of a short paper it would be impossible, as it is indeed unnecessary, to deal with points of interest in individual cases of fever. I shall merely direct attention, firstly, to the types of disease met with during the epidemic; secondly, to the constant phenomena or peculiarities which existed in the prevailing fever—viz., typhus; and thirdly, I shall briefly discuss the probable etiology of the latter.

TYPES OF DISEASE MET WITH DURING THE EPIDEMIC.

The chief types of disease met with during the epidemic were simple continued and enteric fevers, diarrhoea and dysentery, and typhus.

The chief features of interest in connexion with the enteric cases were the almost uniform occurrence of epistaxis, the frequency of melæna, and the great emaciation of the patients. One presented the conditions described by Allbutt as a rare sequela of enteric fever—extreme marasmus, sunken eyes, a dry harsh skin, and a state of complete apathy. In almost all the enteric cases rachialgia, severe arthritic, osteal, and abdominal pains were complained of—the three former evidently of a neuralgic character. These, with the usual relapses of enteric fever, have led in some instances to the mistaken diagnosis of relapsing fever. Throughout the union under my own observation there were nineteen cases of enteric fever.

Closely allied to the enteric cases, both as to causation and symptoms, were those of diarrhoea and dysentery. In each it was the rule for all the members of a family to suffer from one or other of these affections, and in all an exciting cause could be satisfactorily traced. A water-supply from a well into which sewage matter of every nature freely passed, collections of all kinds of filth poisoning the air of the huts in which the people live, and a dietary consisting almost exclusively of Indian meal, badly cooked and often used without milk, are, I think, factors quite adequate to produce an outbreak of disease. During my visit to the union I examined 21 cases of diarrhoea and dysentery. The effects of an altered dietary were shown remarkably in the diminution of the number of such cases and in the improvement of those who had been affected. Oatmeal was given uniformly with Indian meal; whilst to those who were ill, flour, milk, rice, arrowroot, and Liebig's extract of beef were supplied. The instructions given by the Local Government Board to supply liberally whatever was required by the sick were fully complied with, and at the time I left the union no fresh cases of diarrhoea and dysentery were reported, and all who had been under treatment were convalescent.

Typhus fever.—Some idea of the extent and severity of the epidemic of typhus fever may be realised from the return of cases admitted to Swineford Fever Hospital from the different dispensary districts and from the workhouse from the 1st March, 1880, when the epidemic may be said to have first manifested itself, up to the 31st July.

Admissions from Foxford Dispensary District	13

" Swineford " " "	39
" Workhouse " " "	8
Total admissions...	96
Typhus ...	84
Enteric or simple continued fever ...	12
Deaths from enteric or simple continued fever	0
Deaths from typhus ...	13

Out of the 13 fatal cases 6 were over fifty years of age. In the entire union, from June 1st, 1880, to July 31st (I select this period as the information which I have obtained relating to it is, I consider, the most accurate), there were 179 cases of fever reported. Out of these, 140 were cases of typhus, of which 19 died, showing a mortality of about 13·5 per cent.

The influence of age on the rate of mortality is partly shown by the following table:—

Deaths from ten to twenty years ...	5
" twenty to thirty years ...	3
" thirty to forty years ...	4
" fifty years and upwards ...	7

I have not been able to procure a sufficiently precise account of the ages of all the persons affected during the epidemic, so I cannot as yet say whether or not the death-rate has been peculiarly high or low at certain ages. The great proportion of cases occurred between ten and twenty years.

PHENOMENA PREVAILING IN THE EXISTING DISEASE.

I shall now briefly direct attention to the symptoms which were more or less constant in their occurrence in the cases of typhus under observation in the hospital, and to those which were anomalous. I shall not allude to the symptoms usually met with in the disease.

Physiognomy.—General absence, except in the aged, of flushed face and congested conjunctivæ.

Eruption.—In 10 per cent. of the cases no eruption could be observed. In one it was distinctly raised through the entire course of the disease, and accompanied by miliary vesicles, which appeared upon the trunk and extremities. The skin in many cases was so dark and bronzed that the eruption was with difficulty discerned. This discoloration (*Vagantenfärbung*) was evidently the result of exposure and want of cleanliness. In two cases, both fatal, large ecchymoses made their appearance upon the back and legs, and after death large black stains upon the trunk were observable. There were, however, no external hæmorrhages in either case. In no case were there signs of scorbutus. As is usual where crisis takes place by sweating, sudamina upon the chest and abdomen were developed. The odour from the skin was most pungent in some cases, and, as a rule, *sui generis*. I believe that from the nature of the food used by the people, and the insufficient attention to personal cleanliness, a peculiar odour from the body is generated quite independently of disease.

Temperature.—Very high temperatures, even in the bad cases, were the exception, the highest temperature recorded amongst all the cases in hospital being 105·2° F.

Circulatory system.—Pulse very markedly and constantly irregular in the serious cases. Heart-sounds of the character usually met with in adynamic typhus.

Digestive system.—One of the most constant features of the epidemic was the condition of the tongue. It was coated with a long, milk-white fur, sometimes dotted at the sides with enlarged red papillæ, and in adults towards the later periods of the disease becoming dry and brown, in a well-defined band in the centre. In children the creamy whiteness continued throughout the fever, without showing any tendency to dryness. Save this, there were no special phenomena referable either to the digestive or urinary system that call for observation. In only two cases were diarrhoea and meteorism present.

Respiratory system.—In old people a marked tendency to death from suffocative catarrh existed. Three patients had well-defined cerebral breathing.

Nervous system.—In a small proportion of cases delirium—typhomania—existed. Four adults died in profound coma. In one case, that of a boy aged twelve, very marked cerebrospinal symptoms manifested themselves—cephalalgia, with constant screaming, cerebral vomiting, and retraction of the head. Under active treatment—leeching the temples,

blistering the nape of the neck, and the frequent administration of full doses of bromide of potassium and antimony—the symptoms subsided and the patient is now convalescing.

Nutrition.—In the great majority of cases emaciation was a prominent feature; this was specially observable in children.

Duration.—The ordinary duration of the fever was fourteen days, but it was prolonged in four cases to thirty-one days. The usual forms of crises were met with, that by sleep being the most common.

Relapses.—Four cases in which a relapse of fever occurred have been noted. In two, a pyrexial attack, lasting some four or five days, seized the patients—in one instance a week, in the other a fortnight, after convalescence from typhus. Both were caused by a surfeit. A third case of relapse of a nature similar to the preceding was traceable to premature and excessive fatigue. In the fourth case, an adult patient had, it is stated, well-marked maculated typhus, from which he recovered and was discharged from hospital. Three weeks afterwards I examined this patient at his own house, where I found him lying. He had at the time the symptoms of typhus in a marked degree, except that there was no eruption observable. The attack lasted for twelve or thirteen days, terminating in recovery.

ETIOLOGY.

I have purposely left the question of the causation of the epidemic for the last, as it is naturally the point upon which information is most desired, not alone for present, but for future guidance. During this and the two preceding years, there has been a steady increase in the number of cases of fever in the Swineford Union, chiefly typhus in type. The Registrar-General's returns show, that whilst in 1875-76-77 the number of deaths from fever throughout the union reached 13, 18, and 16 respectively, in 1878-79 the numbers of deaths were 36 and 48; whilst in this year up to July 31st 37 deaths from fever have been registered, as contrasted with 28 for the same period of last year. Though this return does not indicate any very considerable increase in the extent or virulence of the prevailing fever, it is important to note that during 1879 an epidemic of typhus fever of considerable extent occurred in the union, especially in one of its districts. The medical officer of the district referred to, had under observation nearly 300 cases of fever during 1879, or in the enormous proportion of 1 in 40 of the population, under his charge. During this year the number of cases of fever has been remarkably small, whilst in most of the other districts of the union there has been a striking increase.

I do not consider that this is the place to enter into the consideration of the political or social causes which combine to keep the people of this union in a state of chronic destitution. The union is, I believe, one of the poorest, in Ireland, as a reference to its rates and valuation will show. A moderate increase in the normal state of poverty of the people produces a crisis like that through which they have just passed. A fair estimate of the extent of the destitution which prevailed may be shown from the facts that during the distribution of the charitable funds, relief was afforded to 43,000 persons out of a gross population of 54,000, and that in one parish of the union containing over 1600 families only 100 are above a £4 valuation. That this state of chronic destitution exercises some influence in converting endemic typhus into an epidemic can hardly be doubted. I have already, in a published report, referred to insufficiency of food, or food of an unvarying nature, such as Indian meal, cooked always in the one way, as *predisposing* to the spread of typhus fever, by lessening the resistance-power of the individual to infection. But there cannot, I conceive, be the least doubt of the *exciting* causes of the epidemic in Swineford Union being contagion, and, in the few instances where this could not be traced, overcrowding, favoured by bad ventilation and absence of cleanliness, personal and otherwise.

That the want of the ordinary necessities of life must have been a fruitful source in the propagation of typhus may be shown by taking one circumstance into consideration—viz., want of clothing. In times of distress clothing of all kinds is pawned to procure food. It is then quite usual for a family of five or six persons to sleep in the one bed, owing to the dearth of bedclothes. The habit of the poor people is not to send at once for the dispensary medical officer in cases of illness, except in those of a painful nature. The result is that when typhus attacks an indi-

vidual in a short time most or all of the members are struck down. Amongst the cases brought under my personal observation I have only noted three or four instances where this rule did not obtain; in some cases seven, and usually four or five, members of a family being attacked. I need not point out how greatly this intensifies their distress.

The tendency to the spread of typhus is, moreover, greatly aggravated by the dislike of the people generally to go to hospital, whilst there is no possible means afforded in their single-roomed cabins for even an approach to any measure of isolation. In many of the huts in the rural districts the amount of cubic space allotted to each individual is considerably under 200 cubic feet, whilst the only means for ventilation afforded is by the chimney, if such exist, and the chinks in the door.

The bad sanitary conditions of the rural districts of the union, and the effect they exercise upon the generation and propagation of disease, have been already adverted to. The wretched condition of the people in this respect is not the growth of this year, and, where everything is so defective, I quite admit that sanitary prescriptions seem more or less illusory. But it must be borne in mind that the extreme poverty of the people renders the carrying out, under present circumstances, of many of the most important provisions of the Public Health (Ireland) Act impracticable. Nor could they, if enforced, correct habits more widespread than even the cause which produced them. Any suggestion which I ventured to make in reference to sanitary improvements, or otherwise, were intended merely as palliatives; they were called for in the presence of an epidemic, and I think I may say that their adoption, as far as was practicable, and the facilities of every kind that were afforded for dealing generally with the epidemic of fever, have helped to produce the desired effect.

That some vigorous measures are required to obviate this tendency to recurrent periods of distress and their attendant epidemics must, I think, be obvious to everyone. The public works which are being undertaken will, doubtless, exercise for a time a most beneficial influence in this direction.

I cannot help doubting if those who speak of rooting the people in the soil—people “too thick upon the ground already”—are personally cognisant of the social misery and helplessness of the inhabitants of the rural districts of that part of the west of Ireland which I visited during my recent inspection.

A PUZZLING CASE OF CANCER OF THE LUNG.

BY SURGEON-MAJOR W. CURRAN, A.M.D.

A DELICATE, scrofulous-looking lad of ten was struck on the left side, just outside and below the nipple, on or about the 24th of April, 1879, by the shaft of a grocer's truck, which he was trying to steady from the front while other children pressed it downwards from behind. The blow caused some pain, which was, however, referred at the time to the effects of the strain he sustained on being forcibly raised upwards, and when brought before me, on the first day of the following month, for the swelling that ensued, I regarded the latter as nothing more than an ordinary strumous abscess. I had it poulticed and fomented accordingly; the boy was ordered to be kept quiet in bed, and to take beef-tea and syrup of iron. His temperature was 104° on this date, and the general appearance indicated debility and malaise. The details are compressed to the utmost, to save space; and I refrain, for the same reason, from all collateral comment or comparison.

Finding that the swelling continued to increase, while there was also some fever, I punctured it with the smallest trocar available here, on the 29th of May, and drew from it a few drachms of pure arterial blood. I then informed the parents of the gravity of the case, and added that it might be necessary for me to open the swelling and secure the vessel—assumed at that time, and indeed subsequently, to be one of the intercostals—but they did not relish this proposal, and I did not consider myself justified in enforcing

compliance with it, even if I had the right or power of doing so. I waited accordingly till the Deputy-Surgeon-General of the district came round on his visitation, and then brought the matter to his notice. He appeared to think with me, that one of the vessels of the side, external to the chest, had given way under the strain described above, and the result of our consultations was that “we determined to watch the progress of this swelling, and interfere as soon as it appeared that it was increasing in size, or that its contents were undergoing a degenerative transformation.” The temperature usually stood at 101·3° about this time, while the pulse ran at times up to 130, and he was allowed beef-extract two pots, and port wine two ounces daily.

Kindly aided by Dr. Manifold of Liverpool, I aspirated this tumour on June 14th, and drew from it three ounces of clear, frothy blood. There could be no doubt on this point, for I examined the blood under a powerful lens, and found it to partake of all the usual characteristics of that fluid. He bore the procedure, as well as the chloroform, well; but the gravity of the prognosis was, we both thought, considerably enhanced by the results of our interposition, and my colleague counselled abstinence and gentle uniform pressure to the side. This, however, could not be carried out, owing to the irritability and noisy protests of the lad himself, and meantime, the pulse having run up to 140 while the temperature remained steady at 103·3°, I examined the chest, and found some evidence in it of a localised attack of subacute pneumonia of the left apex posteriorly. No breathing could be detected lower down on either side, and the percussion note was dull in the same quarters. Respiration was, in short, mainly carried on through the right lung, and the heart-sounds were found to be much more perceptible on the right side than they were on the left. There were some threatenings of bedsores; the temperature had fallen to 101·3°, while the pulse varied from day to day, according as he slept or otherwise, and the case looked now more unpromising than ever.

I aspirated the tumour again on the 23rd of June with Dr. Cavanagh of Liverpool, and drew off about three ounces of fluid watery blood. This coagulated after the usual fashion, but presented an excess of white corpuscles, as compared with the former specimens under the microscope, and we finished the proceeding by injecting about half an ounce of perchloride of iron into what we both regarded at this time as a large hæmatocele or collection of bloody fluid. The pulse was 130 the following morning, and the temperature 103°, and I again wrapped the swelling in sheet lead, over which I placed layers of cotton-wool, which were themselves kept *in situ* by a kind of binder or corset we extemporised for the purpose. But whether due to the iron injection or not I could not say; it became so tense and painful as to necessitate the removal of the compress, and the heart was this day found to be clearly displaced to the right. The breathing was found to be quite puerile on the right side, while though all but suppressed in front on the left its character had improved towards the apex posteriorly, and the tension of the swelling was relieved by occasional watery exudations. The temperature remained steadily about this period at 100°, while the pulse fluctuated between 130 and 150; the respiration sometimes reached 40. He complained of a pain in the neck, which was probably due to the increasing size of the tumour, and the skin over the latter was so thin and discoloured as to threaten rupture at any moment.

Fancying that something more might be done for him, or rather reproaching myself for not having interfered more actively before, I asked two friends from the town to see him with me on the 2nd of August, and they, after carefully measuring the growth and examining the lad himself generally, advised me to leave it and him alone. They came to this conclusion chiefly, as I understood, on the grounds that the boy could not safely bear much rough handling, and that the loss of so much blood might prove fatal on the spot. Moreover, nature appeared inclined to open an issue for its more gradual escape, and as regards the measurements just referred to, the left or affected side measured nineteen inches and a half, while the right measured only thirteen. The swelling itself measured loosely around its base some seventeen or eighteen inches, and it appeared on this occasion almost as large as an ordinary fetal head. Other consultations and measurements took place later on, but with the same general result, and as the opinions advanced were either not unanimous or were so tentative and dubious as scarcely to deserve that designation, I refrain from giving them in detail here,

and will only add that the case being henceforth regarded as hopeless, such measures of support and relief, local and otherwise, as were in my opinion best calculated to afford both were unsparingly applied by me. All to no purpose, however, for he lost a considerable quantity of blood from the tumour on the 10th of August, and at frequent intervals subsequently, and the left or affected side was found to measure, on that date, twenty-one inches, while the right only measured fourteen.

The feet began to swell on the 13th of August, at which time the swelling itself measured from above downwards twelve inches and a half, laterally twelve inches, and circumferentially around the base nineteen inches. The urine was free from albumen or other abnormal element, and the side generally exhibited a soft, sloughy, half-putrid appearance. A medical friend, who kindly came some distance to see him with me on the 22nd, surmised that the excrescence now communicated with, if it did not originally emanate from, the chest itself. Nay, he even hinted a suspicion of its being aneurismal; and the displacement of the heart—now of several weeks' standing,—as well as the compressed, inelastic condition of the left lung, lent, it must be allowed, some support to this view. I could not, however, accept it; the more so as the pulse, always quick and irritable, never presented a decidedly hæmorrhagic character, and there was an entire absence of abnormal vascular sound or impulse in the growth. So also was there an entire absence of hereditary taint; while the fact of the blow was obvious and recent, and everything pointed to the effects of this as the cause of his sufferings. The swelling of the feet extended, about this time, up towards the knees, and the superficial veins of the trunk, but especially so those of the left chest, became simultaneously tortuous and dilated. The vessels of the right neck throbbed much more violently than those of the left, and he could not rest long—if he may be said to rest at all—in any one position. His sufferings and irritability, all along very considerable, had ere this quite exhausted the patience of even his parents, and his weakness was now such as to lead to the belief that the end could not be long delayed.

The body gave out a sickly cadaveric odour on Sept. 5th, and his exhaustion and impatience increased apace. The tongue became dry and coated on the same day, but he would take no medicine, and as to a subcutaneous injection of morphia, or other local application, it was quite out of the question. He cried out as I approached him on the morning of the 6th that he was dying, and the general appearance did not belie this assumption. He lost about a pound and a half of bloody fluid from the surface of the tumour on the morning of the 7th, and this appeared to bring matters to a crisis, for the breathing was thenceforth gasping and difficult, and the pulse so feeble and flickering as to be almost, if not quite, imperceptible. Fortunately the sensibility had been so numbed by the bleeding as to minimise the suffering, and retaining his consciousness to the last he died "hard" about 11.45 A.M. of the same date, or within 141 days of the day on which he had sustained the injury alluded to above.

On section twenty-three hours after death the body was found to be extremely emaciated, reduced, in short, to skin and bone, and there was little or no rigor. The feet and legs were both puffy and œdematous, and the skin had sloughed over a considerable portion of the tumour towards its apex. The left or affected side measured from the ensiform cartilage in front to the spine behind, over the tumour, eighteen inches, from above downwards the length of the mass was eleven inches, and circumferentially—i.e., loosely about the base—it measured twenty inches and a half. It had a soft boggy feel, and a flabby pultaceous resistance, and its surface was pervaded by large and prominent veins.

On opening the thorax and abdomen by the usual incision, the left lung, so enlarged as to push the heart over to the right side in front of its fellow, was found to consist of a malignant mass of medullary cancer, which had eroded the bodies of the seventh, eighth, and ninth ribs, and escaped, by the entire destruction of the eighth, through the thoracic wall. A section of it, which Dr. Klein was kind enough to examine for me, "possessed a stroma of thinner and thicker trabeculæ of fibrous connective-tissue, which anastomosed into a meshwork. The meshes or alveoli of this stroma are," he adds, "filled with closely packed nucleated cells. The cell substance is very scarce, while the nucleus is irregular or spherical," and the decomposition of the specimen I sent him precluded any further or more searching examination.

Added to its continuation, which broke down under traction into a grumous and purulent-looking fluid débris, the mass weighed 4 lb. 14 oz., and the right lung was quite healthy. The muscular tissues of the heart were pale and anæmic, and the liver-texture exhibited a perceptibly amyloid reaction. There was no appearance of fat anywhere throughout the body, and the other viscera were free from taint.

Remarks.—Acknowledging with some feeling of compunction, but without any shame, my own gross, palpable, and profound misconception of the "point" of this case *ab initio*, ay, and almost *usque ad finem*, I must observe that I did not stand alone in this respect, and that this was only the third example of its kind that has come under my notice during a professional career that now exceeds twenty-six years. The other two occurred many years ago, one in a London hospital at which I happened to be a clinical clerk, and the other in a soldier at Pembroke Dock, South Wales. The former provoked a good deal of diagnostic refinement and argumentation at the time, but its precise character was, as far as I can now remember, never entirely realised; and my present case elicited at best only a dubious or hesitating adhesion to its nature on the part of one or two of those who saw it. Not so that of the soldier, which was gauged at once through the secondary glandular swellings it produced in the neck. And the other instances of cancer that I have seen during my twenty-three years' service were two of the liver, one of the parotid, and one of the testicle.

Moreover, I was prevented by the boy's waywardness and irritability from thoroughly examining him for many days, I may almost say weeks, before his death. He objected to all interference on our part, nay, indeed, cried bitterly at the mere suggestion of it, and I was afraid he might shriek his life away on the spot. Again, the blood and the blow misled me, as they did others, and we never even suspected that the external tumour was a continuation of the lung. One gentleman did, indeed, feebly hint at its being a hernia of that organ, but the objections to this were overwhelming, and the displacement of the heart was ascribed to effusion from within the chest, or to the access of blood to its cavity from without. The dulness and dilatation of the intercostal spaces were compatible with either assumption, and the persistence of respiration before and behind, lent some support to these views. So also were the anæmia and wasting his frame exhibited. And as to the so-called "cancerous cachexia," or its congener, "that peculiar sallow complexion," which is so characteristic of malignancy, they were simply conspicuous by their absence.

The only case at all resembling it that I can find in the few books at my command occurred in the hands of Dr. Leared, and is reported by that gentleman in the 21st volume of the Transactions of the Pathological Society of London, page 60. From this it would appear that a tumour, "the size of half a goose's egg, bulged from under the scapula on the right side of a man of sixty-eight. The long axis of this growth, which encroached upon the axilla, was perpendicular, and the mass extended two inches lower than the anterior line of dulness. The tumour was somewhat tender on pressure, of firm consistence, and perfectly dull on percussion. Marked dulness also existed over the lung posteriorly from its summit to a line drawn horizontally from the lower edge of the tumour to the spine. The lateral intercostal spaces beneath the tumour were in the natural state, and on section about two-thirds of the upper portion of this lung had been transformed into an encephaloid mass, which it was impossible to remove from the body without disruption. . . . The external tumour was ascertained to be composed of a continuation of this mass, into which portions of the first, second, third, and fourth ribs had been, as it were, fused;" and, except that the base was the seat of the mischief in my case, while the apex was more involved in the other, the resemblance between the two was very strong. The disease appears to have been confined in this also, as in mine, to one lung; and the amount of rib-tissue destroyed, as well as the other general results, "prove the growth to have [had] an intense power of local infection" in both.

Warrington.

THE visit of the Duke and Duchess of Connaught to the North London Hospital for Consumption, which was arranged to be made in the present month, for the purpose of laying the foundation-stone of new buildings in connexion with the institution, has been postponed until October next.

A MODIFIED INFLATER FOR THE MIDDLE EAR.

By EDGAR A. BROWNE,
SURGEON, LIVERPOOL EYE AND EAR HOSPITAL.

THE Politzer method of inflating the middle ear is attended by some inconveniences much resented by children and nervous females. Children especially are apt to bungle over the swallowing, and to suffer from the water being driven backwards into the throat or out by the lips from imperfect closure of the palatal veil. True, we can always inflate an obstinate child's ears when it cries, but we do not always want to be making children cry, and it has seemed to me that a pleasanter process might be advantageously devised.

When we expire forcibly by the mouth, the soft palate is drawn up and the passage of the air outwards by way of the nostrils is absolutely prevented. If, therefore, we conduct the expired air into the anterior nostrils by means of a tube, we shall be forcibly blowing into a closed space, and as the soft palate is drawn up the Eustachian tubes are presumably open. Such is the case. A convenient instrument is made by fitting an ivory mouth-piece to an india-rubber tube four inches long, terminating in Allen's nasal pads. The patient has simply to fit the pads to his nostrils, take the nozzle between his lips, and blow into his own nose. A little teaching is occasionally required. Some patients allow a good deal of windage between the tube and their lips; others ingeniously place the tip of their tongue over the orifice of the nozzle, and only succeed in puffing out their cheeks. Some cannot adapt Allen's pads closely to the nostrils; for them an ivory or vulcanite nozzle, with a rounded end that can be held in the nostril, is preferable. The forcible passage of the air into the tympanum has been verified many times by the diagnostic tube.

The method has the recommendation of extreme simplicity, rendering it widely applicable for home use among patients who require daily inflation. The absence of preparation robs it of half its terrors for children, who can be taught to inflate their own ears as a pastime.

HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

CHARING-CROSS HOSPITAL.

RUPTURE OF AXILLARY ARTERY DURING REDUCTION OF LUXATION OF THE HUMERUS; DIFFUSE TRAUMATIC ANEURISM; AMPUTATION AT THE SHOULDER-JOINT; DEATH; REMARKS.

(Under the care of Mr. BELLAMY.)

RUPTURE of the axillary artery associated with simple dislocation of the humerus, or occurring during the reduction, is an extremely serious accident, though, happily, rare. In one case in which dislocation of the humerus was complicated by diffuse traumatic axillary aneurism, Mr. R. Adams reduced the dislocation, and then ligatured the subclavian artery. The patient recovered. Most of the cases of rupture of axillary artery during the attempts at reduction have been in dislocation of some weeks' duration. Indeed, it is probable that the rupture of the artery is due to laceration of the adhesions formed around the displaced bone in the neighbourhood of the vessels. In the subjoined case no attempt at reduction seems to have been made for at least six weeks. In that time firm adhesions had doubtless formed. If the statement of the patient may be trusted, the rupture of the axillary occurred during the reduction. Unfortunately the

mode of reduction is not stated. When admitted into Charing-cross Hospital there was only one alternative. The man must be left to bleed to death or amputation must be performed through the shoulder-joint.

For the following notes we are indebted to Mr. Whitehead, surgical registrar:—

J. H—, aged fifty-five, dislocated his right humerus on Dec. 16th, 1879; and in the following month he went to a large metropolitan hospital, where the house-surgeon put him under an anæsthetic and attempted reduction. On Feb. 2nd one of the surgeons made further attempts, and the patient stated that he immediately became aware of a swelling in the armpit. A fortnight after this he was discharged. He had lost sensation since the time of the last attempt. Three weeks after he left the hospital a little bright blood oozed through the skin, and on July 30th he had more severe hæmorrhage, losing about a quarter of a pint of arterial blood, and then the bleeding ceased.

On admission, situated in the region of the right shoulder was a large tumour. The walls were very tense, and pulsating. The clavicle was distinct, and not involved. The pulsation was best felt at the posterior part of the axilla. The arm below was much swollen and waxy; no pulse could be felt at the wrist. At the lower part of the tumour, in the axilla, the skin was dark and sloughy, from which flowed a watery discharge. The tumour was not distinctly circumscribed at its lower margin, and was about as large as a man's head. The patient was anxious in appearance, and stated that he had been rapidly losing health since the appearance of the tumour. He had had no attacks of syncope or breathlessness, and the face was not markedly blanched. Pulse 96; respiration 18. Conjunctiva and mucous membrane pale and anæmic. He had slight cough and watery expectoration.

After consultation with Mr. Amphlett (who admitted the case from his out-patients) and his other colleagues, Mr. Bellamy determined on amputation through the shoulder-joint. This was done by commencing with an anterior flap, from without and *not* transfixing. Although the subclavian artery was most efficiently compressed by Mr. Bloxam, the hæmorrhage on the first sweep of the knife was terrific, the blood coming from the tense sac and from the enlarged vessels behind and below. The second or posterior flap was cut after disarticulation, in a few seconds, and some pounds of clot and organised lymph were removed.

The main trunk, as far as its topographical position should have been, was not recognisable. There was a hard cartilaginous-like tube on the wall of the thorax, throwing a fearful jet of blood, and which, notwithstanding the pressure on the subclavian artery, was secured after great difficulty. After all bleeding points had been secured the flaps were adjusted and the patient removed to bed. Unfortunately, he never rallied, and about an hour afterwards died.

NEWARK HOSPITAL.

A CASE OF QUASSIA POISONING.

(Under the care of Mr. D. T. RECKITT.)

ON June 30th, 1880, Annie B—, a girl aged four years, was taken to the hospital by the mother, who stated that for several weeks it had suffered from prolapsus recti after action of the bowels, and that it had very frequent desire to go to stool, remaining sometimes half an hour on the seat, straining violently. She had never seen any thread-worms, but fancied all her children had them. Suspecting that ascariæ was the cause of the prolapsus, the nurse was ordered at 1.30 P.M. to give an injection of six ounces of simple infusion of quassia. With the exception of a tablespoonful all was retained, and the child taken away. At 3 P.M. the mother returned, saying that the child was only just alive, she having in the meantime taken it to a friend's house. She also stated that in taking it from the hospital it reeled very much, as if tipsy, and that she was obliged to carry it to this temporary lodging. Mr. Reckitt visited it at once, and found it in an alarming condition, reclining on the knee of a woman present. It was ghastly pale; the lips were bloodless, the head thrown back, the surface cold, eyes closed and pupils contracted, with no action to light; respiration inaudible, and the pulse not to be felt. It was quite unconscious.

The feet were placed in very hot water, which immediately roused the child with a violent scream. Some strong brandy

and water was given and swallowed with difficulty, but the pulse returned. The child was kept roused by having the feet placed occasionally in hot water and mustard cataplasms applied to both calves. There seemed to be a strong desire to sleep, when the pulse became much slower and more feeble, so the feet were again put into hot water, and small, but strong doses of brandy were given internally. After an hour and a half the child vomited once, and then seemed a little better, but continued quite unconscious. Half a drachm of ether, one drachm of compound spirits of ammonia, and half an ounce of brandy, diluted with warm water, were injected into the rectum, and retained by means of the finger applied to the anus. This acted most favourably, for the colour returned to the lips and face, the surface became warm, and the breathing and pulse more natural. During all this time, except when allowed to sleep, it moaned very much. The colour, respiration, and pulse being much improved, the child was allowed to sleep. At six the child was roused, and a little brandy was given. At 6.30 P.M., it was conscious, and looked quite well, though sleepy. Some cold milk was ordered. The quassia injection did not act as a purgative, the bowels not having been moved since its visit to the hospital.

Remarks.—From inquiries afterwards it was ascertained that the dispenser had by mistake placed the concentrated infusion in the bottle set apart for the simple infusion, and thus an over-dose of quassia had been given; and added to this, its entire absorption had produced these most alarming symptoms, which, from first sight, seemed to threaten to prove fatal. In this dilemma, and knowing no antidote, but believing its toxic effects to be exerted on the nervous system as a narcotic and depressant, as the symptoms plainly indicated, the hot water was resorted to first to rouse the child, and then stimulants to complete its safety.

BOROUGH HOSPITAL, BIRKENHEAD.

TRAUMATIC CARDIAC HERNIA.

(Under the care of Dr. LAMBERT.)

FOR the following interesting notes we are indebted to Mr. Grenfell Baker, M.R.C.S., senior house-surgeon.

P. R.—, aged forty-eight, was admitted on March 4th, with the following history:—While engaged unloading some bars of iron on board a ship by means of a crane, one of the bars slipped from a height of about ten feet above him, and its point struck him over the region of the heart. The bar was stated to be about twenty-five feet long and three inches broad. He was immediately rendered insensible, and remained in that condition about half an hour, when, having partially recovered consciousness, he was conveyed to the hospital.

On admission he was in a collapsed state, and spoke with difficulty, the effort required for so doing appearing to cause him great pain. Very great pain was complained of over the cardiac region, and on examining this spot comminuted fractures of the second, fifth, and sixth ribs were found. On coughing or deep inspiration, a very prominent bulge occurred over the site indicated. The tumour thus formed extended above the surrounding surface about an inch, and measured two inches across, and beat synchronously with the pulse.

The parts were gently pressed into position, and a shield of tin covered with lint was adjusted over the broken ribs, and firmly strapped to the left side of the chest, and a broad bandage was applied over all. Perfect rest in the dorsal position in bed was enjoined, and frequent small doses of opium given.

No bad symptoms occurred till the fourth day, when the pulse rose from 70 to 100, and the temperature from 98.8° to 102°, and some difficulty in breathing, and pain over the injured parts, were complained of. Auscultation revealed nothing abnormal, and two days later the patient's condition returned to the normal. Three weeks after his admission into hospital the ribs were found to be firmly united, and the heart and lungs appeared to be in a quite healthy condition. The shield was ordered to be worn a fortnight longer, and patient went home in all respects quite well, and he has since never complained of any discomfort referable to his injury.

Remarks.—From the great weight of the bar of iron that

caused the injury in the case, and the height from which it fell, striking the man directly with its point, it appears very remarkable that greater damage was not done than actually occurred. This case also shows that, although the pericardium must have been a good deal irritated, both from the force of the blow in the first instance, and the friction of the broken ends of the ribs against which it pressed when the heart protruded, yet no inflammation or other trouble arose, and the heart itself escaped all injury. The insensibility was very profound and immediate, and lasted nearly half an hour, and the general condition of shock for six hours.

Reviews and Notices of Books.

Contributions to Orthopædic Surgery: including Observations on the Treatment of Chronic Inflammation of the Hip, Knee, and Ankle-joints by a new and simple method of Extension; and Lectures on Club-foot. By JAMES C. HUTCHINSON, M.D., Surgeon to Brooklyn City Hospital, &c. New York: G. P. Putnam's Sons. 1880. — The opening chapters of this book describe a very simple method of treatment for chronic inflammation of the joints of the lower limb at any stage. The objects aimed at are fixity of the joint, extension, removal of the weight of the body, and exercise in the open air. Dr. Hutchinson claims to secure all these advantages by allowing his patients to get up, with a high patten on the sound foot and with crutches. In this way the diseased limb is raised from the ground and the weight of the body removed from it, while its own weight acts as a constant extending force, which can at any time be increased, if necessary, by adding weights to the foot; the spasmodic contraction of the muscles acting on the diseased joint maintains it fixed. Under this treatment it is asserted that pain and swelling subside, and the limb assumes its proper position. For the knee- and ankle-joints light splints of hatter's felt are required to assist the muscles to fix the bones. If the treatment be as successful as it is stated to be, its advantages are very obvious, for it is simplicity itself. We quite agree with the author that the muscles of the hip fix that joint far more securely than any apparatus. The lectures on talipes are very simple and commonplace. More care in revising the proofs would have been an advantage; it is rather too bad to have a woodcut of the os calcis called the astragalus twice over!

House Architecture. By J. J. STEVENSON, Fellow of the Royal Institute of British Architects. Two vols., large 8vo. London: Macmillan and Co. — "To build a house for oneself," says Mr. Stevenson in the opening paragraph of this charming work, "is an excellent education in architecture. By the time it is finished, and the owner has lived in it, he feels how much better a home he could build with the experience he has acquired if he had to do it over again. While the work is going on his attention is called to questions he had never thought of before, which are now of the greatest interest to him. He examines the houses of his friends, and discovers features in them which he wishes, when too late, he had introduced in his own plans. The designs are altered, and the cost increased. His taste in architecture and his ideas about planning are changed by his new experience, the building is too far advanced to adopt improvements, and the house which he had hoped would be perfect is a source of trouble and disappointment." From a writer who holds so justly sympathetic a view of the troubles and disappointments of the householder—heedless of the experiences of his fellows, particularly of those pounds, shillings, and pence experiences which have recently been so pathetically set forth in the columns of *The Times*—some help ought to be obtained in minimising the difficulties which make house-building one

of the most perplexing and aggravating of enterprises. And it must be confessed that Mr. Stevenson's work will do much [to smooth the path of the unhappy individuals who cannot resist the temptation to meddle with bricks and mortar. It is also of interest for the information it gives as to architecture in relation to house-building, and from the excellent manner in which it treats of the principles of house-planning. It is a work to delight the eye, as well as to improve the mind, from the beautiful manner in which it is illustrated, and the goodness of its typography. The entire "getting-up" of the work, indeed, does honour to Messrs. Macmillan's press, and to the artists who have been engaged in its production. The greater part of the work is necessarily devoted to architectural details, but so much of it as is particularly given to the more strictly sanitary considerations of heating, water-supply, and drainage, is sound in principle. This is especially noteworthy, as it must be confessed that architects are too commonly deficient in knowledge on these important points—a knowledge on which the comfort and health of the inmates of a house are largely dependent. We commend this work most heartily to our readers, not only for the special knowledge it contains, but also for its general interest on a subject which appeals more or less to everyone.

The Therapeutics of Gynecology and Obstetrics. By W. B. ATKINSON, M.A., M.D. London: Baillière, Tindall, & Cox. —This work only calls for brief notice. It professes to give a summary of the methods now adopted in the treatment of the diseases of women. Its plan includes a synopsis of the diagnostic points of a disease, a description of the various methods used with a view to cure, and a *résumé* of the remedies employed. The synopsis of diagnostic points is short, and of no particular value. The descriptions of the methods of cure form the chief part of the work. These are given usually in the words of authors who have written upon the subject. Indeed, the work has been made up from the writings of authors whom the editor is pleased to call "distinguished contemporary specialists." If the work will serve no other purpose, it shows the unscientific, chaotic condition of the "therapeutics of gynecology."

Transactions of the American Gynecological Society. Vol. IV. 1879.—This volume is quite up to the average of its predecessors. All the papers in it are contributed by American physicians, except one, which is by Mr. Spencer Wells. This is a case of removal of both ovaries for dysmenorrhœa (Battey's operation), and illustrates well the difficulties of the operation, and the accidents that may befall a most experienced ovariotomist. Several questions of the greatest interest are discussed in the volume, of which intra-uterine medication, introduced by Dr. White and Dr. Batley, and prolapse of the ovary, by Dr. Mundé, may be more especially mentioned. Dr. Reeves contributes a very interesting case of extra-uterine pregnancy, which was cured by the application of electricity. A paper by Dr. Van de Warker on "The Relation of Symptoms to Versions and Flexions of the Uterus" leaves the subject in as unsatisfactory a state as ever. The volume contains also an interesting paper on Justo-minor Pelvis, by Dr. Lusk; one on Chronic Inversion of the Uterus, by Dr. Byford, in which the author reverts to Dr. Tyler Smith's plan of restoring the inverted organ by means of pressure, exercised by an elastic bag introduced into the vagina. At the end of the volume is a valuable index to the works published on gynecological subjects during the previous year.

MESSRS. W. J. ADAMS & CO., of Fleet-street, have issued a sixpenny *Improved District Railway Map*, which cannot but be found extremely useful to persons who have to travel much about the great city.

ENTERIC FEVER IN TROPICAL CLIMATES.

To the Editor of THE LANCET.

SIR,—I am glad to observe that the question of "enteric" fever in India continues to obtain attention, and as I believe, from the discussion which has already taken place on this subject, that the differences of opinion regarding the disease so called are really more as to its name than its reality, I propose, if you please, to briefly comment on the substance of a letter regarding it, which appeared in THE LANCET of 31st July, 1880.

What, then, is the precise sense in which the term "enteric" is applied by the writer of that letter to the fever in India which he describes? If to a fever the result of endemic and climatorial influences acting upon particular diatheses, and individual conditions,—the fever itself becoming in its course complicated with intestinal, that is, *enteric* ulceration,—there is no question that such a species of fever does occur among British soldiers in that country.

But inasmuch as the *definition*, according to which my inquiries were conducted, was "a specific fever with enteric ulceration, due to the presence of filth in air, earth or water," not one of the cases, the reports of which were brought before me, as a matter of fact came up to that definition.

In the same letter, reference is made to certain temperature standards as diagnostic of "enteric" from malarial fevers. In my special reports from Madras, copies of which I had the honour to transmit to you, not only do the standards of temperature charts which I give in the first of these documents differ absolutely from each other, but the charts of individual cases given in my second report are in complete disaccord with each other, as they are with the *standard* given in your correspondent's letter. And so, with the other phenomena of individual cases given in my reports, they are in disaccord with those recorded in the same communication.

Your correspondent alludes to "post-mortem appearances pathognomonic of enteric fever." So far as the extracts from authorities and writers given in my reports justify a conclusion, that conclusion is that in fatal cases of fever due to *pythogenic* causes, there are no post-mortem appearances of a nature beyond such as exist in fatal cases of non-specific fevers due to endemic and climatorial causes in India; also, that appearances undistinguishable from them occur in other diseases than fever, and as results of certain poisons.

Your correspondent admits that it is hard to obtain positive evidence as to the pythogenic nature of *enteric* fever in India. With reference to the cases recorded in my reports, I remark again, that, by the showing of individual medical officers, no such evidence was actually demonstrated, although often assumed, to the relative omission of due consideration, I fear, of such general conditions of climate, season, and "endemic" influences as were actually the cause.

As I have observed in my reports, the circumstance that the relative mortality by fever in India has of late years increased, and that too since the more general spread of the *pythogenic* theory as against the *climatorial*, indicates that the time has fully arrived for a reconsideration of the subject with reference, at least, to British troops in that country.

Yours faithfully,

Cambridge Gardens, W.

C. A. GORDON, Surgeon-General.

THE "City Press" records the presentation of a testimonial to the senior medical officer of the City of London Infirmary, consisting of an elegant silver salver, which bore the following inscription: "Presented to Charles Hope Buncombe, F.R.C.S., by the officers and assistants of the infirmary of the City of London Union, August, 1880." The address bore the signatures of the whole staff. The following is the inscription: "To Charles Hope Buncombe, Esq., F.R.C.S.—We, the undersigned officers and assistants of the Infirmary of the City of London Union, beg to offer you our sincere congratulations on the dismissal of the unfounded charge of manslaughter brought against you; and as a slight memento of our sympathy for the anxiety and annoyance you have passed through, we ask your acceptance of a silver salver, with our best wishes for your future health and happiness."

THE LANCET.

LONDON: SATURDAY, AUGUST 14, 1880.

THE trial of PLEASANCE LOUISA INGLE, a nurse of Guy's Hospital, for the manslaughter of LOUISA MORGAN, a patient under her care, is happily without precedent, and we have the authority of Sir H. HAWKINS, the presiding judge, for stating that a hospital nurse has never before been tried on a charge of criminally neglecting a patient. Medical practitioners have often been compelled to undergo a trial for manslaughter, but in such cases any nurses who may have been implicated have been considered merely as the instruments of their chief's treatment, and not themselves responsible. This trial has taken place, not probably because the nurses of the present day are either more or less humane than their predecessors, but rather because one who is the representative of a vicious "system" (so-called) of nursing, has discovered too late that those who assume the dignity of responsibility must be prepared for the consequences of their assumed position.

The facts of the case are simple enough. The deceased, LOUISA MORGAN, was admitted to Guy's Hospital on June 9th, 1880, under the care of Dr. PAVY, who considered her to be suffering from consumption, affecting chiefly the left lung, and hysteria. On or about June 25th it was directed that she should be got up, in order that she might not become weaker. On July 2nd she complained of pains in the left leg, and on July 5th she had an evacuation of the bowels in the bed. This was the *vera causa* of the trial. INGLE, about 8.30 on the morning of July 5th, asked CROCKETT, the "sister" in charge of the ward, if she might give MORGAN a cleansing bath, as she had soiled the bed in the manner stated. Deceased was made to walk to the bath-room in her night-gown and boots about 8.45, and at 10.15 she was still in the bath-room. It was conclusively proved that for a great part of this time she was sitting in an almost empty bath, with water nearly cold (the "hot" water being only tepid at that hour of the morning) "nearly covering her hips." It was proved also that on her way back from the bath the deceased dragged one leg, and that the prisoner "jumped" the deceased, and handled her violently, saying, "It is obstinacy; you can walk if you like." On July 5th Dr. PAVY saw the patient three times. On the first occasion, between three and four, he was "struck by her altered appearance." She was feeble, cold, and shivering, and made a disconnected statement as to the treatment she had received, and cried and sobbed a good deal. At the second examination, Dr. PAVY found bruises on her body, on both arms, and abrasions on the skin. At night her condition was unaltered. On Thursday, July 8th, the symptoms of tubercular meningitis were fully established, and on July 22nd LOUISA MORGAN died.

The questions for the jury to decide were two in number. 1. Had the prisoner, by administering the bath in the manner described, been guilty of "gross and culpable" misconduct? On this head they had presumably

no difficulty in coming to a conclusion in the affirmative, for witnesses on both sides admitted that such a bath was unwarrantable, and indeed it would have been unwarrantable to have administered such a bath in such a manner to a healthy woman. And to a woman suffering from tubercular disease, no matter of what organ, such a bath would be a grave source of danger. 2. Had the bath hastened the patient's death? "If," said Sir H. HAWKINS, "it was accelerated by a single day, that in the eye of the law would be manslaughter as much as if the death had been accelerated by years." Seeing that the only medical witness for the defence (Sir WM. GULL) admitted that the giving of such a bath to a patient with the symptoms presented by the deceased would be "most improper," and that the only possible reason for this opinion would be the danger of aggravating the disease and accelerating its termination, the jury naturally came to the conclusion, in the absence of any difference of opinion between the medical witnesses as to the main point at issue, that the prisoner had been guilty of manslaughter. She was accordingly sentenced to three months' imprisonment without hard labour.

The defence was singularly lame and impotent. It consisted in an endeavour to show that the prisoner was warranted by Dr. PAVY's view of the case in doing what she did, and that it would not have been grossly culpable to have treated an hysterical woman in the way described. Dr. PAVY's diagnosis was proved to have been from the first one of "phthisis," a diagnosis which the post-mortem proved to be correct. Dr. PAVY said that the deceased had some "hysterical symptoms," but there was no evidence that he had ever regarded hysteria as anything more than quite a secondary element in the case, or that he had given the least countenance or encouragement to any such brutal and obsolete treatment as that pursued by the prisoner. Sir WILLIAM GULL's evidence was clearly intended by Sir JOHN HOLKER to produce the impression that Dr. PAVY's view of the case was not a correct one, or at least less correct than that which would have been taken by Sir WILLIAM GULL, who figured before the jury as a prophet of past events, a *rôle* which it is easy enough to play. But there was no evidence whatever that Dr. PAVY's view was ever anything but correct, for up to July 2nd there had been no symptoms of brain mischief. On that day there was pain in one leg, a subjective phenomenon to which no physician of large experience would pay any great amount of attention. Dr. PAVY did not see the patient again until July 5th, and in the interval there had occurred the involuntary evacuation, the dragging of one leg, and the bath, and from that time the character of the case was clear. There can be no doubt that the brain mischief had begun before the bath was given, but the elements for a diagnosis clearly did not exist before July 5th, on which day the criminal act of the nurse took place. The post-mortem showed old and recent tubercular disease of the brain; to what extent the bath and its attendant excitement had contributed to the establishment and aggravation of the latter was the point most difficult to determine, and one concerning which no wise man would, we think, be inclined to speak dogmatically.

THE lamentable occurrence in Guy's Hospital has served to bring into light again certain clinical and pathological

problems, which are of grave importance, not merely with regard to the present case, but to many other like cases. The case seems to us to afford another illustration of the great difficulty which attends the recognition of the initial symptoms of cerebral tuberculosis, and the need of further study of the causes which excite or accelerate the progress of the disease. Setting aside all the other points which may be raised with regard to the case, and the various opinions which have been expressed upon it, we shall endeavour briefly to discuss it from a clinical and pathological point of view, and try to arrive at an independent opinion as to its clinical history. This we can unfortunately only do upon very incomplete data, for the entire clinical and pathological record has not been published. It is due to the eminent physicians who have expressed different opinions upon the case, and to the profession at large, that this record should be published in full at as early a date as possible, in order that a correct judgment on the points at issue may be arrived at.

The points which seem especially to require consideration are—(1) What was the condition of the patient previous to the giving of the bath on July 5th, and how far was her condition calculated to excite any suspicion of cerebral affection? (2) Did the giving of the bath produce or merely coincide with the onset of graver cerebral symptoms? (3) Is there any reasonable ground for a belief that it excited or intensified the more acute cerebral inflammation which caused the patient's death?

The main facts of the case are already before our readers, and we will restate only such as may require to be emphasised.

The patient, LOUISA MORGAN, a married woman twenty-six years of age, was admitted, on June 9th, to Guy's Hospital, under Dr. PAVY, with consumption associated with hysterical symptoms. From the history it appeared that she was married at an early age, had one child about a year afterwards, had since suffered from symptoms of pelvic inflammation, though whether of the nature of pelvic cellulitis, ovarian abscess, or what not, we are not told. The lung disease did not appear to be advanced or active, but there were considerable weakness and irregular slight febrile temperature, pointing to some progressive tuberculosis. But for about a month, from June 9th to July 5th, there were no other notable symptoms beyond those described as hysterical. The question of the nature of these hysterical symptoms becomes important in the light of the subsequent events. They appear to have consisted in a disinclination to exertion, complaints of vague wandering pains in the limbs, for which no cause could be discovered, and now and then some transient sense of weakness in one or other limb, equally inexplicable by her general condition. It is not surprising that these symptoms, lasting as they did for some weeks, with no definite cerebral symptoms, should have led to the supposition that they were of a "hysterical" nature. After all, hysteria is a term which is very loosely used, and is often employed to denote merely a certain combination of defective will-power, and a tendency to exaggerate slight symptoms, which are common enough in sickly women. There are few medical men, we imagine, who do not very frequently speak of such a condition as "hysterical," but who would draw a sharp line between a "hysterical patient" and a patient with hysteria. It is easy to be

wise after the event, and to discern in these vague symptoms the indications of a cerebral disease which was discovered after death, but we have no evidence that there was anything upon which to ground a diagnosis at the time. Indeed, we may go further, and say that a very large number of cases of chronic tuberculosis affecting the cerebral hemispheres are not only not diagnosed, but that they may give rise to no appreciable symptoms. And it is incredible that in a hospital like Guy's, which abounds with acute clinical observers, such symptoms should not have been detected or suspected had they existed in any marked degree. At the same time it must be allowed that there is often in the general condition, the facial expression, and the mental attitude of the patient, a ground for suspicion and anxiety such as appears to have been felt in this case, apart from any declared symptoms, and that the commencing mental inertia and torpor, simulating wilful obstinacy, especially if combined with pain in the limbs, hyperæsthesia, or temporary weakness of one limb, are always to be regarded with suspicion.

Coming now to the time of the bath. It appears that this was given in consequence of the patient having fouled the bed. It is almost clear from the way in which this was treated by the nurse, that it was regarded as merely an exaggeration of a wilful, obstinate, and careless condition which had previously existed, and which she regarded as deserving of punishment. It is strange indeed that no one of the nurses or the sister of the ward should have seen in this a grave symptom of cerebral disease. Apart from involuntary defecation in some cases of diarrhoea in phthisis, or some local disease of the rectum, we are not aware that this would be likely to occur in such a patient except as the result of cerebral or mental disease. If there were evidence that such an occurrence had previously been reported, or having occurred, had failed to be reported, a grave oversight on the part of the sister or the house-physician must be assumed; but there is no hint that such was the case. We may rather regard it as the crucial point of the diagnosis, which would declare plainly that the vague symptoms previously observed were really indicative of grave disease of the cerebral hemispheres, such as was actually found to exist after death, unless, indeed, there was local mischief in the rectum connected with the pelvic abscess.

Turning now to the condition at the time of and after the bath, and the question how far the latter may have excited or accelerated the acute inflammation, we find that the patient evidently underwent a very severe shock, both mental and physical. Terror and anxiety were combined with a prolonged exposure to one of the most powerful depressants known; with the manifest result of a collapsed physical condition, added to a state of anxiety and fright. But it may well be asked whether this could possibly cause acute tubercular meningitis, and whether in the present case there is any reason to believe that it actually did so. As regards the possibility, it must be allowed that we know very little of the exciting causes of tubercular meningitis. There is, however, a gradually accumulating mass of evidence that both local and general conditions may determine the incidence of tuberculosis on a particular organ or part of an organ, and there is no reason to believe that the brain is any exception to this rule. If, for example, in a

patient with slowly-progressing tuberculisation of the lung, there is by any means excited an acute inflammation, this is very apt to be accompanied or succeeded by especial deposit of tubercle in that part; it may become, in fact, either a tubercular inflammation, or may tuberculise instead of resolving. The immediately exciting causes of tubercular meningitis have been very incompletely studied, but no fact seems better established than that the inflammation is often quite disproportionate to the amount of tuberculosis, and that it often appears to be rather a sequel to, than a concomitant of the latter. Cases occur to our mind in which the symptoms certainly appeared to be directly excited by some exposure to cold or mental shock. There is therefore some ground for the belief that these may have been operative in the present case. But does the clinical evidence bear out this view? If it is urged that the carelessness about the evacuations was a symptom of acute tubercular meningitis, it would of course be idle to seek any subsequent cause. In the absence of evidence of other brain disease this might perhaps be fairly alleged, but the more chronic tuberculosis appears to be a sufficient and more probable cause, though the symptom is rare in both forms. It is stated also that no more definite symptoms of inflammation appeared for three days afterwards, during which time the temperature continued low, and the patient apparently under the influence of a mental shock. Death did not occur until sixteen days after the bath. In the absence of fuller information we cannot follow the case. It would be of great value to know what the course of the symptoms was, in order to judge how long the active symptoms were in progress. But having in view the great variety in the course and duration of tubercular meningitis, we should hesitate to draw any absolute conclusions. The duration, indeed, is often very much shorter than fifteen days from the first declared symptoms, a fact which favours the view that the onset was excited by the bath. It would, however, be very difficult to allege with certainty that the bath was the exciting cause of the meningitis, or that it might not have occurred without its influence. The direct evidence of the marked change in the patient's condition is here of value in forming an estimate of the probabilities of the case.

If it were not travelling somewhat beyond the immediate questions at issue, it would be of interest to consider the various modes of manifestation of acute tubercular meningitis in the adult. The distinction drawn between the results of chronic tuberculisation, yellow tubercle nodules in the cerebral cortex, or more rarely in the more central portions of the brain, and acute meningitis, usually of the base, is not always sufficiently borne in mind. The diagnosis of the more chronic form is, we do not hesitate to say, judging from the recorded experience of many physicians, a matter of the greatest difficulty. Such cases, especially when in the adult and affecting the cerebral hemispheres only, have been diagnosed as syphilitic, as pachymeningitis, as acute meningitis, or chronic rheumatic meningitis, even by the most able physicians. On the other hand, in a not inconsiderable number of cases of acute tubercular meningitis, the earlier symptoms are purely mental, and very frequently simulate hysteria or hysterical mania, the mental symptoms being far more predominant in the early stages in adults than in children. We have known a case to be regarded as

one of hysteria till within twelve hours of the fatal issue. Such facts should lead to caution, both in making a diagnosis and in expressing an opinion as to facility of diagnosis in any particular case.

It cannot be disguised that the professional aspects of the case REGINA v. INGLE are very grave and call for serious, albeit strictly impartial, consideration. The appeal now lies formally to the Censors' Board of the Royal College of Physicians, but that body has, on former occasions, scarcely shown the wisdom, tact, and independence which would entitle it to the implicit confidence of the profession at large, and the case must therefore be judged by another tribunal—namely, medical opinion. Looking at the matter from this point of view we cannot but feel that the questions at issue between Sir WILLIAM GULL and Dr. PAVY are of a nature to require very careful but exhaustive handling. The broad facts are fairly before us, and we see no reason to withhold an expression of opinion which may or may not accord with that formed by the College of Physicians, but will, we believe, be that at which the profession ultimately arrives.

The first question that arises is whether the step taken in this most deplorable case was determined upon at a formal meeting and after a general consultation of the medical staff, or was the independent act of Dr. PAVY, who considering the circumstances found himself unable to give the usual certificate of death? Looking to the exceeding magnitude and importance of the medico-legal issues to be raised, we think it was due to the hospital as a medical institution, and the profession as represented thereby, that a previous deliberation should take place. The need of such a precaution has been made painfully evident by what has ensued. For example, if there had been a preliminary consultation, no question could possibly have been raised at the trial or elsewhere as to the character and value of the clinical notes of the case and the record of the post-mortem examination, upon which the conflicting opinions expressed were based. It should have been clearly settled at the outset whether the documents to which we allude were or were not the private property of the physician in attendance on the case. If they were regarded as private, we are at a loss to understand how they came to be placed before any members of the staff without the consent of the physician to whom they belonged. If, on the other hand, it was held that these records were the property of the hospital, then they must be assumed to have been at the disposal of the governing authority of the hospital. It argues a surprisingly strange state of matters that so simple a point as this should be involved in obscurity. Either there is a clinical record kept in each case, to which the governors may have access—although it is difficult to divine for what purpose the lay authorities of a hospital can need to refer to a medical and technical report—or the papers were the property of Dr. PAVY alone. If they belonged to the hospital, the governing body of the institution had certainly a right to submit them to whom they pleased, and particularly to the consulting officers. If they were the private property of the physician to whose case they related, and were to be used in evidence at the trial, they ought to have been submitted to both sides previously. It is a rule of practice in courts of law, and one which ought to be observed in all

these matters, that the papers which relate to a dispute are either "put in" or not quoted. The opinion given in evidence by Sir WILLIAM GULL was based solely on the data supplied by these papers, which he seems to have seen without the knowledge of the physician in charge of the case, and the profession should be informed as to their nature.

The appearance of Sir WILLIAM GULL in the witness-box, in a position even seemingly antagonistic to the medical staff, is greatly to be regretted. Such a spectacle would probably have been prevented by a general consultation. Sir WILLIAM is the senior consulting physician to the hospital, and as such holds an office the first and principal obligations of which are towards the working staff. Nothing short of a subpoena—unfortunately compelling the intervention of a consulting officer as a witness to give critical evidence on the work of his colleagues—could, in our judgment, have justified his appearance before the Court. Once in the box, it is easy to see that he must speak the whole truth, and therefore state fully and clearly his views. The question in which the profession has an immediate interest is whether the data upon which Sir WM. GULL arrived at a conclusion, differing widely from that of the physician who had seen the case, were of a nature to compel the line of conduct he pursued. It must be conceded that a physician can be ruled only by his own judgment in the opinion he forms of a case, and his own conscience must determine the course he takes in expressing that opinion. We have no right, and certainly no desire, to obtrude considerations of professional interest or etiquette between conscience and conduct; but if ever there were circumstances in which a physician so placed must see cause to question his sense of duty, those by which Sir WM. GULL found himself encompassed when he opposed his judgment (of a case he had not seen, on the ground of the report of a post-mortem examination at which he had not been present) to that of the physician—a colleague and a man of acknowledged eminence in the profession—who had treated the patient and personally examined her body, were of that character. Look at the matter as we may, it is impossible not to feel that the conviction that there had been an error in the diagnosis of this case must have been *very strong indeed*, and the pressure of duty to humanity and justice—a pressure we distinctly recognise and respect—must have been exceedingly great to satisfy a man of high and honourable instincts that duty compelled him to a course from which every other feeling must have recoiled.

We have no wish to over-estimate the obligations of professional etiquette. There may clearly be circumstances amid which such considerations must sink into comparative insignificance. Still less would we willingly say anything, or pursue a line of argument, which might seem to treat the inter-relations of members of the medical body as of a nature to override the paramount claims of public duty; but it is not expedient that professional obligations should be lightly set aside. It will be necessary to hear more of this matter than we have yet heard before a definitive judgment can be pronounced; but the opinion of the profession must be the ultimate court of appeal, and by the unwritten law of the medical body as interpreted by the common-sense instinct of its individual members the final award will be made. If, in the course of the inquiry which must ensue, the relations,

obligations, and responsibilities of a consultee—whether in relation to the governing body and medical staff of a hospital, or to the family and ordinary medical attendant of a private patient—can be more clearly defined than they seem to be at the present moment, good may come out of evil, and this we are convinced will be a result over which every one interested in, or concerned with, this most painful controversy must find occasion to rejoice.

OUR readers may remember that last year the Select Committee of the House of Commons on Medical Bills were disappointed in not receiving the evidence of Mr. BRADFORD, the courteous representative of the Apothecaries' Company in the General Medical Council. Mr. BRADFORD was indisposed, and unable to give his evidence. The circumstance was the more to be regretted as several witnesses, while admitting that the Society had done good in the past, had advocated the view that it was no longer necessary in the economy of things, that it was decidedly superfluous, and its further continuance, with a seat at the Council, scarcely defensible. Yet every Englishman is interested in the defence set up for an old institution. Though we are a progressive people, we like to see a good fight made by the friends of what is established and incorporated. Hence it is gratifying to us to be furnished with a copy of the evidence which Mr. BRADFORD intended to have given before the Committee, in refutation of adverse evidence given by various witnesses. The reasons for excluding the Society from further representation in the Medical Council, and excusing it generally from further work in the medical examining system, were briefly these:—1. That there was a sufficient number of examining bodies without it, and that it was unjustifiable to ask that it should be maintained in perpetuity. 2. That room was needed in the Medical Council for the direct representation of the profession, and that one way of creating such room was by discontinuing the representation of certain bodies, including that of the Apothecaries' Society. 3. That the Apothecaries' Company was ceasing to be a licensing body. 4. That the Society was more or less a trading company.

The evidence before us, which we may hope will one day next session be actually put before a Select Committee, is not a satisfactory or convincing refutation of the arguments of those who seek to elevate and simplify the organisation of the examining bodies and to improve the constitution of the Council. In effect, it aims at proving two points: First, that the Apothecaries' Society, as such, never was a trading company, though it allowed some of its members, formed into a copartnership, to carry on for their personal benefit the business of chemists and druggists in the name of the Society. Admitting this, it must yet be conceded that the Society was in close contact with trade; the more so as, under the deed of the Joint Stock Company, it was required that its business should be conducted by thirty shareholders, all of whom were to be members of the Society or Corporation, and practising apothecaries, and eight of whom were to be members of the Court of Assistants (the governing body of the Society or Corporation). Besides this, the Master and Wardens of the Society were, in addition, *ex officio* members of the Committee of Management. Surely all this was sailing very near the *trade* winds. It

will be seen that we have used the past tense, for in a note added it is said that "since the evidence was prepared, the United Stock of the Society of Apothecaries has (from circumstances in no way connected with the question raised before the Select Committee) been dissolved. *The relation therefore (the italics are ours) hitherto subsisting between the Society and that body has entirely ceased.*" We congratulate the Society on the cessation of a relationship that was decidedly objectionable. The coincidence of this cessation with the public objections to it is curious, but we must accept the assurance that it is accidental.

The other objection which it is attempted to refute in the evidence is that "the Apothecaries' Company is fast ceasing to be a licensing body." Mr. BRADFORD'S answer is this: "As a matter of fact, the average of licences granted by the Society between 1870 and 1879 was about 213 annually, showing the Society to be numerically the second licensing body in the three kingdoms." The objection is put in too strong language, which always tends to defeat the object in view. Nevertheless, it probably remains true that the Apothecaries licence is not in so much demand as it used to be, and it certainly is true that there is no reason in the public interest, as there is none in public law, why men entering the profession should ally themselves with a Society which reminds us of a somewhat low conception of the medical function, and of a time when the body of the profession was thought to be of a different brand from that of the consulting class. We willingly admit that the Society has done good service, and did at one time the work of the College of Physicians, because that College, as it does yet sometimes, conceived very erroneously and inadequately of its great duties. But seeing that the Colleges are now driven by the force of public opinion to higher conceptions of duty, and that medical men now aim at being not "apothecaries," but veritable physicians and surgeons, and seeing further that the Apothecaries' Society cannot, by the very terms of its own creation, give a perfect examination, we can certainly perceive no adequate reason for the further continuance of the Apothecaries' Society as an examining body, with a seat in the Council.

Annotations.

"Ne quid nimis."

TYPHUS IN IRELAND.

IN another part of THE LANCET we publish an important paper from the pen of Dr. Nixon, on the epidemic of "Fever" in the Swinford Union, County Mayo. It must be obvious to those who give careful attention to Dr. Nixon's statements that the Government has been perilously near to the point of committing, if it has not actually to some extent committed, the blunder which converted the famine in Southern India into so awful a disaster—namely, underrating the effects of chronic starvation upon the distressed communities in Ireland. The condition of the patients suffering from "fever" as described by Dr. Nixon, and the number and peculiarities of the cases of diarrhoea and dysentery in the union, prove that although deaths from *starvation* may have been staved off, it by no means follows that the hardly less considerable and not seldom fatal mischief arising from chronic starvation has been obviated.

The conditions under which typhus and enteric fever are

observed in the union (apart from the immediate distress) are such as to give rise to the gravest considerations. They are conditions by no means limited to this particular district of Ireland. It is difficult to realise a state of existence which at the best is barely distinguishable from a condition of chronic starvation, and circumstances of housing and habits of domestic life which are revolting in their disregard of what we look for amidst a civilised community. The endemicity of typhus and enteric fever in the district, as described by Dr. Nixon, is the normal result of such conditions. When last we referred to this subject we spoke of the application of the provisions of the Public Health Law to Swinford Union and districts similarly situated in despairing terms. Dr. Nixon's paper does not permit us to regard the subject from a more hopeful point of view, but it enables us to form a juster estimate, perhaps, of what is needed if we look for a better sanitary future of the districts referred to. Obviously no merely palliative measures, such as have been chiefly in view, or measures determined solely with regard to the present distress, can be regarded as sufficient. What is needed is the institution of measures founded upon a comprehensive view of the requirements of the districts, and an administrative organisation which can be depended upon for carrying them out with certainty, however slowly, and with due regard to the impoverishment of the people and their rooted habits: a hard and it may be a thankless task, and one which looks to the future rather than the present—a task which has regard to the next generation and even to the generation following.

Dr. Nixon's paper further suggests a question for our consideration in England which is worthy of immediate consideration, and which we commend to medical officers of health. The migration of labourers from Ireland to England in the autumn still continues, although in less proportion than was the case when machines had not invaded agricultural regions. Swinford contributes a considerable number of labourers to our harvest fields, and it is well that the medical officers of health of our western ports and rural districts should be alive to the probability of the labourers from the districts in Ireland where typhus now exists bringing the disease in their train.

THE METROPOLITAN WATER-SUPPLY.

THE report of the Select Committee on the expediency of acquiring on behalf of the inhabitants of London the undertakings of the existing metropolitan water companies, has been published. It leaves the question pretty much as it was before the late Government took it in hand, deciding against the provisional agreement with the water companies, which they had promoted, and making certain suggestions which we should venture to term crude, if crudeness dare be inferred of the proceedings of a committee of selected members of the Legislature. They hold it expedient that the supply of water to the metropolis should be placed under the control of a Public Body, to be created for the purpose, and which shall represent the interest and command the confidence of the ratepayers. This public body they think should, in the absence of a single municipal body, which could undertake the duty, include elements derived from the Metropolitan Board of Works, the Corporation of London, and representatives of those districts beyond the limits of the metropolitan area to which the companies distribute water. But this body, besides having to look to a greater efficiency, economy of water-supply, and equality of charge than now exist, will have to give regard to arrangements for extinction of fire, and the making of better provision for the health of the community. Nevertheless, no suggestion as to the manner in which this new body is to secure competence in its judgment on the complex question of health is made, and the

Committee repeats the common politico-social blunder which is perpetrated on the assumption that everyone is fitted to express an opinion and act upon it in regard to such a matter. The Metropolitan Board of Works, as now organised, is notoriously incompetent to deal with health questions, and the Corporation, although capable of dealing with questions of health within its municipal limits, is scarcely fitted to deal with such questions as they affect the whole metropolitan area.

The new public body formed would be called upon to consider first how it should proceed about what it was created for. It might adopt various courses with this object. The Committee tells us, it might proceed by regulation of the powers of the existing water companies, as in the case of gas-supply; or by the introduction of an independent water-supply; or by the purchase of existing undertakings. In either case Parliament would have to intervene by giving statutory powers other than now exist. In short, we must begin again at the beginning, and, whether we like it or not, settle matters with the existing water companies before we can take a single certain step in advance. Moreover, the question has as yet been raised only as regards now existing London and its environs. But these change every year, and each year adds to the difficulties of the question to be solved. And if our readers would learn what the future question of the water-supply of the metropolis and its dependencies is likely to be, let them turn to a most thoughtful and instructive article on the subject by Mr. F. R. Conder in the present month's number of *Fraser's Magazine*.

THE STARVATION CASE AT HASTINGS.

EMILY SCOTT, a schoolmistress living at Hastings, was convicted, at the Central Criminal Court, on Saturday, August 7th, before Sir Thomas Chambers (the Recorder), of withholding food from her servant, Eleanor Houseman, aged fourteen, whereby her life was endangered, and she had suffered bodily harm. She was sentenced to two years' hard labour in the House of Correction. The history of Eleanor Houseman is inexpressibly sad, and proves the correctness of the trite saying, that "truth is stranger than fiction." The child is illegitimate, was born somewhere in the north of England, and lived with a Mrs. Crosby, of Scarborough, until she was twelve years old. Early in the year 1878 Mrs. Crosby placed Eleanor Houseman in the train at Scarborough, and she was received at King's Cross by a Miss Jackson. Mrs. Crosby stated in evidence that the girl left her house "because a Miss Jackson wanted her;" she had never seen Miss Jackson; she did not know what became of the child's mother; she had never seen the child's father. Thus this unhappy foundling, scarcely twelve years old, was sent into bondage among strange people in a strange land. She first lived with Scott at Dulwich, in 1878, twenty pounds being paid with her, on the understanding that she was to be made a servant or a governess according to her capacity. Scott moved to Sandwich in 1879, and subsequently to Hastings, where the alleged crime was perpetrated. It appears that at first the poor child associated with the other children of the "school," but was afterwards banished to a garret because she stole food, and henceforth became a miserable little drudge. That she was practically starved was conclusively proved. She was fed principally upon porridge, which was often mixed with cod-liver oil, and sometimes with charcoal; but nothing seems to have been too nauseous to repel the craving appetite of the child. The room in which she lived was cold, and on a bitter day in February she was seen cleaning windows with nothing on but a chemise and pinafore. It was proved by Dr. Ashenden, and confirmed by Dr. Parsons, that on February 28th of this year, Eleanor Houseman was reduced by this treat-

ment to a very critical and dangerous condition. She was thirteen and a half years old, and weighed 35 lb.; was pinched and emaciated, and covered with chilblains, some of which "broke," and led to sloughing of the toes and necrosis of the phalanges. Scott expressing herself as unable to provide proper nourishment, the girl was removed to the infirmary, Dr. Ashenden humanely supplying some necessary medical comforts, and luckily for Miss Scott this timely care and treatment saved the life of the child, who rapidly gained flesh, and on July 7th of this year weighed 83 lb., having gained rather more than 5 oz. per diem for 129 days. In defence it was urged that Miss Scott was very poor, and that the diet of herself and her scholars was scarcely any better: "But," said the Recorder, "poverty was no excuse, as the workhouse was always open for her to shift her responsibility upon." It was also urged that the child's critical condition was due to hectic fever, brought on by the wounds on the feet, but the Recorder very properly urged that "the proof of illness was in the remedy applied. The child was starved, but with food rapidly recovered. Physic was necessary for the diseased, but food was necessary for the famishing, and food, and food alone, was administered to her, and nothing else was required." Of the justice of the conviction and sentence there can be no doubt. The reflection which forces itself upon us is that it would be a great gain to the public and the cause of humanity if the care of foundlings and orphans were to some extent controlled by the State. Poor Eleanor Houseman has been treated with no more consideration than if she were one of the lower animals, and to all practical intents and purposes she was sold into bondage. A solemn duty rests, we think, with the public at large, to render the recurrence of such a scandal as this impossible. Surely it is time that those who make a business of receiving children who are repudiated by their parents should be licensed and supervised, in some such way as are those who receive lunatics and others who cannot take care of themselves. From an economic point of view it is everybody's interest that these unhappy waifs and strays should, if possible, be trained and developed into useful citizens, and not be allowed, by a course of starvation and ill-treatment, to become a burden to others either in workhouses or prisons.

NERVE INFLUENCE ON THE TISSUES.

SINCE the year 1869 Dr. Brown-Séquard has noted the power possessed by the central nervous system, under the influence of certain irritations, to arrest the nutrition in different tissues and organs. The maximum arrest of the interchange between the tissues and the blood is produced by a puncture near the point of the calamus scriptorius, but it is also caused by stimulation of other parts of the cerebro-spinal centre, and even of the sensory nerves. After fatal injuries which cause death by sudden arrest of these interchanges, and arrest of the respiratory and cardiac movements, there are no convulsions, the blood in the veins is red, the temperature of all parts of the body rapidly falls; the functions of the spinal cord, of the nerves, and of the muscles are maintained for a long time, and cadaveric rigidity and putrefaction set in late. He has lately found that the medulla oblongata and spinal cord possess so powerful an influence on the interchanges of material of the body that the arrest of these can be produced by merely flexing suddenly the head upon the thorax. Two effects can then be observed—(1) the blood in the veins, previously dark, becomes almost immediately bright red; (2) the temperature of the animal falls. In addition, considerable apnoea comes on. The apnoea would cause the blood in both arteries and veins to become darker, but in spite of this influence the blood, even in the veins, becomes lighter. Dr. Brown-Séquard has often observed this phenomenon in cases of apnoea,

with or without cardiac syncope, produced by irritation of the cerebro-spinal centre of the pneumogastric nerve, or of the ganglia of the abdominal sympathetic. It may be asked, however, whether the effect of the injury to the medulla on the colour of the blood is not due to the stimulation of the alleged vaso-dilator nerves? The following observation disproves the hypothesis. When there is an arrest of the interchange of material between the blood and the tissues, the vessels, instead of being dilated, present a notable diminution of calibre. Dr. Brown-Séquard found that in an animal in which the dorsal spinal cord had been divided irritation of the medulla and spinal cord, such as will cause the effects above described, produces these everywhere, except in the parts which receive their nerves from the portion of the spinal cord which is separated from the brain. Hence it is certain that the effects are produced through the agency of nerves coming from the medulla or cord and acting upon the tissues.

THE CASE OF JOHN WAKEFIELD.

JOHN WAKEFIELD, aged twenty-eight, a labourer, "well instructed," was put upon his trial at Derby on July 28th last, before Baron Huddleston, for the wilful murder of Eliza Wilkinson. The deceased was nine years old, and on April 26th went out hawking comb-boxes with her sister, aged sixteen. Having sold twelve out of fourteen boxes, the sisters separated, and the younger was never seen alive again, but was found shortly afterwards dead, with her throat cut, in one of the houses at which she had presumably called to try to sell a box. The man, having committed the murder, gave himself up to the police. There was no motive alleged for the crime; there had been no attempt to rape the deceased, and there was no evidence that the prisoner had ever seen the deceased before committing the act of murder. The theory of homicidal impulse was put forward for the defence, but the judge in his summing up did not countenance it, and the jury returned a verdict of wilful murder without leaving the box. Sentence of death was passed in the usual form; but while the judge was visibly affected, the prisoner maintained the indifference and unconcern which had characterised him throughout. Not a single witness was called to speak to the prisoner's previous life or history, and he appeared to be perfectly unknown to everybody except the police, who had, it seems, no knowledge of him until the morning when he gave himself up on a charge of murder. The only legitimate presumption in such a case as this is that Wakefield was the victim of an insane impulse, and the burden of proof certainly lies with those who would maintain that his act was a criminal rather than an insane one. The public have a right to be informed of the antecedents of this man, who is reported to be "well instructed." Where do his family live? For whom has he laboured? Is it certain that he has never shown any previous symptoms of insanity? Is he epileptic? These are questions which every humane person would ask before consigning him to the gallows. But they never have been asked (judging from the report of the trial in the *Derbyshire Advertiser*). The prisoner, during the three months of his imprisonment, merely said, with regard to his "crime," that he had "nothing to say"; and he would have been completely undefended at his trial had not the judge on the previous evening arranged with a junior counsel to undertake the defence. One witness only was called for the defence—namely, Mr. Baker, the surgeon to the Derby Gaol; and this gentleman (as he informs us himself) was merely called (and called against his wish) because he happened to be in Court, and the counsel overheard him making some remarks to a friend about "homicidal impulse." Baron Huddleston said that the theory of uncontrollable impulse was "fanciful and imaginary," but said

that all prisoners appeared in the dock charged with similar crimes "because they had not controlled their passions." What passion had Wakefield failed to control? His calmness throughout, and the absence of direct evidence, seem to prove that the passion which he had failed to control was not anger. It certainly was not *lust*. It was proved not to be *avarice*. There was no evidence that it was *jealousy* or *revenge*. The theory of an uncontrolled passion is, to say the least, fully as imaginary and fanciful as that of an uncontrollable (we do not say uncontrolled) impulse. If a man is to be hanged for not controlling his passions, it should be known precisely what were the passions which he failed to control; and, failing this information, we hold that the execution of Wakefield will be a judicial murder of a most flagrant kind.

THE INTERNATIONAL CONGRESS OF HYGIENE OF TURIN.

THE programme of the International Congress of Hygiene at Turin is fixed as follows:—Monday, September 6th: Solemn inaugural meeting, in presence of King Humbert. Speeches will be made by Senator Ferraris, Magistrate of the city; Dr. Fauvel, President of the French Committee; Baron Maydell, of St. Petersburg; Dr. Finkelnburg, of Berlin; Dr. J. G. Jaeger, of Amsterdam; Dr. J. Felix, of Bucharest; and by other delegates on behalf of their respective countries. The report of the Executive Committee will then be read, after which they will proceed to the election of the members to form the Commission empowered to draw up the regulations for the prize of 35,000 francs to be given in 1882 to the author of a useful book on "The Hygiene of Rural Populations," and the Commission to examine the subjects of discussion presented *extra ordinem*. On Tuesday 7th, Thursday 9th, Friday 10th, and Saturday 11th, sittings of the sections in the morning, and general meetings in the afternoon. Wednesday 8th, excursion. Thursday 9th, meeting of the International Association on Drinking Water; communication by M. J. G. Jaeger. Saturday 11th, final meeting. Sunday 12th, excursion to Milan, to witness an experiment in cremation.

DISEASED CATTLE FROM ABROAD.

OUR correspondent at Birkenhead writes:—The s.s. *Iowa*, from Boston, has lately landed 804 head of cattle alive and one dead at this port. Forty-three died during the passage across and were thrown overboard. On beginning to slaughter it was found that some of the cattle were affected with splenic fever. Two carcasses were seized for this cause on the 7th inst., and six more on the two following days. An order to destroy the eight carcasses was on the 9th applied for and obtained. Several of the animals now in the lairage already show signs of the disease, and the slaughtering is being proceeded with under the supervision of the officers of the sanitary authority. The fever appears to be of a mild type, there being no carbuncles, abscesses, or erysipelas. Some of the animals, however, have shown marked head symptoms, and there appears to be no doubt about the malady being really *sang de rate*.

MULTIPLICITY OF THE SPINAL GANGLIA.

THE ganglia upon the posterior roots of the spinal nerves are invariably described as single. A subject has been met with by Dr. Leo Davida of Pesth, in which some of the lumbar ganglia were double instead of single. This observation led him to investigate the condition further, and he has found a similar condition in two other bodies. In some of these the ganglia were treble instead of single. In the first body, that of a man twenty-three years of age, the first, second, third, and fourth lumbar ganglia were double on the

left side, but on the right only the third and fourth. In most the ganglia were quite separate, in some they were connected by a grey commissure. The largest was three millimetres in diameter. The posterior root, two millimetres above the ganglion, divided into two, one for each ganglion. There was a difference in the size of the roots corresponding to the size of the ganglia. In the second body, that of a man forty-five years old, on the left side the first four lumbar ganglia were double, and the fifth was treble. On the right side the first two were double and the last three treble; one of the sacral ganglia was also double. In some instances the three ganglia were quite separate, in others they were united by grey commissures. In the third body, that of a man thirty-two years of age, the third, fourth, and fifth lumbar ganglia were double on the left side, the second, third, fourth, and fifth on the right. As these were the only bodies examined, and the condition was found in all, the conclusion was drawn that duplicity of some of these ganglia is the normal condition. The point certainly deserves the attention of anatomists.

DR. TANNER'S FAST.

THE forty days' fast of "Dr." Tanner was completed on Saturday last without any evil result. It is at present impossible to say what conclusions—if any—can be drawn from it as a scientific experiment, for in spite of the assertion that some of the most eminent physiologists and physicians of New York were convinced of the reality of the fast, there are many points in the statements as to the actual observations during the fast, which tend to throw doubt upon its genuineness. It is impossible to draw any scientific conclusion from the details which have been given in newspaper telegrams, some of which are evidently the work of a very ill-informed person. Thus in one telegram we meet with the statement that on examination of the blood it was found that the red corpuscles rolled together into heaps, which is not an unusual phenomenon, and that they were much crenated, which is a condition easy to produce in careless examinations. We shall await the full record of the experiment—if such it can be called—before we attempt to form any conclusion. We are strongly of opinion that the conditions under which it has been made will deprive it of what little value it might otherwise have possessed.

ROYAL COLLEGE OF SURGEONS.

IN the notice of the meeting of the Council of the Royal College of Surgeons last week it should have been stated that Mr. Le Gros Clark's retirement from the Court of Examiners arises from the expiration of his term of office and his desire not to seek re-election. Mr. Savory's second term of five years as member of the Court has also expired, but he desires re-election. For the vacancy caused by Mr. Le Gros Clark's retirement Mr. Christopher Heath and Mr. Jonathan Hutchinson have been nominated.

THE FRENCH ACADEMY.

THERE was some surprise evinced a few days ago, at the distribution of rewards for virtue, to hear Mons. Sardou, who said: "Virtue is no longer in fashion as it was in 1782, when Monthyon founded these prizes. Virtue!—the nineteenth century scarcely practises it, and does not extol it at all. Its philanthropy takes a different pass. It is no longer the virtuous who interest us, but the criminal. A new philosophy, claiming to be based on science, sees in man nothing but a combination of matter, and declares that his morality depends only on the perfect equilibrium of his organs; and this doctrine having many partisans among medical men, it is not surprising if it sees in humanity only patients. The theory is very precise."

THE GOVERNMENT AND THE ONE-PORTAL SYSTEM.

IT will be seen from our report of the meeting of the British Medical Association that it has been announced there that the Government had decided to bring in a Bill to institute one compulsory qualification for the United Kingdom. We are sorry to have to contradict so good an announcement, but we have authority for saying that it is, up to this time, unfounded.

AT the Leeds Assizes, at the close of an action against the Lancashire and Yorkshire Railway, in which the plaintiff recovered £500 damages for injuries received, Mr. Justice Stephen paid a high compliment to Dr. Clifford Allbutt, Mr. Scattergood, and Mr. Wheelhouse, the medical witnesses engaged in the case. He said he was in the habit of hearing medical evidence in all parts of the country, and Leeds was the only town where he never heard those unseemly disputes between the legal and medical professions which occurred at other places. Here there was a certain number of gentlemen, the leaders of the medical profession in the great School of Medicine in Leeds, who had set an admirable example for many years past of truth and candour and straightforwardness in the witness-box, and he was happy to see that their example was being followed by the younger members of the profession. When a man really tried to tell the truth, the whole truth, and nothing but the truth in plain and simple language, notwithstanding what consequences might be drawn from it, and whether he was called on the one side or the other, bullying in court and things of that kind ceased at once. He hoped that such a state of things might long continue in Leeds, and be imitated in other towns.

THE following extract from the latest report of Mr. Holmes, the Vaccination Officer of Leeds, is worthy of reproduction:—Of 2978 births returned by the registrars for the half-year ending Dec. 31st, 1879, 2627 were registered as successfully vaccinated, 2 were insusceptible, 280 died unvaccinated, 17 were postponed by certificate as sick, 7 were returned to the vaccination officers in whose districts they had gone to reside, 43 were not found, and 2 of the parents were fined for non-compliance with the Act of Parliament. The number vaccinated gives a rate of 88·2 per cent. of the births, and 97·3 of the living children. This is the highest rate yet obtained. Not one child was returned as having suffered from small-pox; 9·4 per cent. died without having had the operation performed upon them.

THE out-patient work of the Newcastle-upon-Tyne Dispensary having largely increased within the last few years, the members of the existing honorary medical staff have found themselves quite unable to cope with the great amount of work thrown upon their hands. The committee therefore, at a special meeting held on Thursday the 5th inst., decided to appoint an additional physician, and generously proposed in future to present each member of the staff with an honorarium at the end of the year.

AN International Congress was held on the 2nd inst. at Brussels, under the presidency of the Count of Flanders, to consider various questions relating to the use of alcohol. The Congress was promoted by French and Belgian societies having as their aim the strict limitation, if not the entire suppression, of the employment of the agent save as a medicine.

M. TRELAT, Professor of External Pathology of the Faculty of Paris, has been transferred to the chair of Clinical Surgery, vacant by the death of Professor Broca.

ON Friday, the 30th ult., the treasurer of the Westminster General Dispensary, Gerrard-street, Soho, entertained, at Willis's Rooms, the medical officers and committee, and after dinner presented to Dr. Waite, the senior physician, a handsome testimonial from the committee and governors, in recognition of his valuable services, on his resigning office after a period of thirty years.

It may be interesting to some of our readers to learn that a committee has been formed at Oxford to collect subscriptions from those who wish to testify their sympathy with Professor Mommsen in the recent great calamity which has befallen him. Subscriptions may be paid to the "Mommsen Fund," at the Old Bank, Oxford.

THE governors of the Royal Berkshire Hospital, Reading, have, it is stated, resolved to provide additional accommodation for the patients. It is intended to expend £10,000 for this purpose.

THE King of Italy has conferred on Dr. Julius Althaus the brevet and insignia of a Knight of the Order of the Crown of Italy.

THE death is announced of Professor Hebra, the distinguished dermatologist of Vienna.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Caistor Rural Sanitary District.—Dr. Alexander Cameron's report for 1879 is the first general report he has had to make, and it refers to ten months only of the year to which it relates. The district is an extensive one, ranging from ten to sixteen miles in different directions from Caistor as a centre. Dr. Cameron's duties during the ten months he had held office in the year had been chiefly devoted to making himself acquainted with the wants of the district, and in initiating and organising systematic measures for its sanitary supervision. His report may be divided into two parts, the first of which is occupied with observations on deficiencies in the law relating to sanitary authorities, and particularly to deficiencies, as he thinks, in the powers they exercise; the second to observations on particular sanitary requirements of his district, and the way in which they should be met. To our mind the second part is infinitely the more interesting and instructive, and we shall trust to hear much more of Dr. Cameron with reference to the subjects of which it treats, and his mode of treating them. Amendment of the law is a very complicated subject, which demands other considerations than those which immediately present themselves to the medical officer of health, and at least its consideration should be deferred until there has been opportunity of testing by experience what can be done with the not inconsiderable powers which the law already gives to local authorities. As a rule, sanitary authorities have shown themselves too little disposed to use their existing powers to make it probable that the Legislature would be eager to increase them largely. With respect to the second part of Dr. Cameron's report it deserves particular notice for the desire that it manifests of studying and dealing in detail with the sanitary defects of rural places, and removing these without having recourse to comprehensive and expensive schemes of engineering and water-supply. We are not prepared to say that his suggestions for obviating excremental and slop-nuisance about houses in rural districts are the best conceivable; but we feel that the habit of thought which he displays in endeavouring to find solutions in detail for the particular difficulties he wishes to have abated is one which requires more cultivation than it has

yet received among the medical officers of health of rural districts. Those who are familiar with the report of the Local Government Board on the means of removing excremental nuisances in towns and villages cannot but feel that there is much more to be done in abating such nuisances in rural districts than has yet been done without the introduction of costly engineering schemes. Dr. Cameron evidently has his own views on this matter; they are clearly of a nature which we desire to see more of; and we shall look with interest for his further experiences.

Dr. Cameron's report gives a curious illustration of the sanitary (or rather insanitary) management of workhouses. He includes in his report an account of the evil hygienic state of the workhouse of the district, and of presumed fatal consequences to some of the inmates therefrom. He notes, moreover, an outbreak of puerperal fever in the workhouse—the nurse of the surgical wards being also the nurse of the lying-in wards!

Birmingham.—Dr. Alfred Hill's report on the health of Birmingham for the quarter ending July 3rd, 1880, shows a birth-rate of 41·6, as compared with 42·8 and 40·2 in the second quarters of 1878 and 1879 respectively, and a death-rate of 19·1 only, as compared with 25·06, 21·35, and 22·04 in the spring quarters of 1877, 1878, and 1879 respectively. There was a great diminution in the mortality from the zymotic class of diseases, the deaths from the seven principal zymotic diseases numbering only 178, as compared with 265 in the second quarter of 1879. The diminution of the mortality from zymotics was observed in each of the diseases in the class except "fever" and diarrhoea. The most fatal of the zymotic diseases was whooping-cough (56 deaths, as contrasted with 122 in the corresponding quarter of 1879); and diarrhoea came next in order of fatality (47 deaths, as compared with 42 in the spring quarter of 1879). The work of privy-transformation seems to be proceeding steadily in the town, as at the end of the quarter it would appear that there were 32,520 privies on the pan-system.

Belfast.—From the report of Dr. Browne, medical superintendent officer of health, presented to the Belfast Town Council last week, we learn that the number of cases of zymotic diseases reported by the medical officers of the several dispensary districts during July, were remarkably few, fifteen cases only having been reported during that period. The total births registered in the four weeks amounted to 508, and the deaths to 359, showing a natural increase in the population of 149. The average death-rate for the month was 27·95 per 1000, calculated on the census of 1871, but on the corrected population it was 22·0.

THE VACCINATION ACTS AMENDMENT BILL.

The Vaccination Acts Amendment Bill has at length been thrown overboard, and the work of the Legislature to this extent lightened—an extent small indeed, if measured by the size of the Bill, but great if regarded from the point of view of the dissatisfaction the Bill gave rise to, and the discussion which was threatened upon it. It would have been mere folly to have persisted with it in the face of the evidence against an alteration of the law of the sort it proposed, supplied by that most excellent of vaccination officers, Mr. Holmes of Leeds, in a recent report presented by him to the Board of Guardians there. Our contemporary, the *Yorkshire Post*, in printing this report, observes that it may please Mr. Serjeant Simon, M.P., to exhibit the neighbouring borough of Dewsbury as a place which prefers a loathsome disease to compulsory vaccination; but that when he couples Leeds with Dewsbury in that preference, he libels Leeds most grossly, as the evidence of Mr. Holmes most fully shows. We print elsewhere a portion of Mr. Holmes' report.

IMPORTATION OF SMALL-POX.

The local journals contain a report of the landing of a small-pox case at Bristol from a vessel bound to Gloucester, and of comments of the Sanitary Authority thereon, which seem to us to betray considerable confusion as to their duties under the circumstances. We have more than once had occasion to observe the imperfect ideas the local authorities of seaports have of the quarantine laws on the one hand, and the powers for dealing with infectious diseases on the other; and we are of opinion that the Local Government Board should take some steps to enable these authorities to see their way more clearly in a complex and not easily understood matter. Between the Quarantine Laws

and the Public Health Laws local authorities are apt to fall to the ground.

DUBLIN COW-POCK INSTITUTION.

During the year ending 31st of last March, 2910 applications were received from medical officers of workhouses, dispensaries, and public institutions, private practitioners, &c., for lymph; and 15,493 points and 2869 tubes charged with lymph were distributed. During the same period 2174 vaccinations were performed at the institution in Sackville-street and the branch in York-street, Dublin.

The report by Dr. Mouat and Mr. Courtenay Boyle on the Infectious Disease Hospital of the Colchester Union is not of a favourable character. The inspectors say, "The hospital is too near to both the workhouse and the outside dwellings to be safe; it is not sufficiently isolated, has no proper separation of the sexes, is approached twice a week by a large number of persons, many of whom are women and children who can hold conversation with the fever patients, and it is administered in an extremely imprudent and dangerous manner." The guardians appear to be willing to set about providing another building which shall be free from these serious objections.

The Guardians of the North Dublin Union have appointed a committee to carry out one of the three principal recommendations made by Dr. MacCabe, Local Government Board Inspector, in his half-yearly report on the sanitary condition of the workhouse—viz., that a small farm should be taken, upon which sheds shall be erected for children, who would there have good air and receive an agricultural training. The other two suggestions—namely, the erection of a small-pox hospital and the enlargement of the workhouse, will be dealt with at a future meeting.

The Royal Assent has been given to an Act entitled the Dagenham and District Farmers' (Optional) Sewage Utilisation Act, and which authorises the formation of a company for the delivery of metropolitan sewage to the occupiers of about 9000 acres of land on the Essex side of the Thames, between Barking and Wennington. Farmers and market gardeners will receive sewage only as they require it, hence the term "optional" in the Act.

The Greenwich Board of Guardians have agreed to a report of their Finance Committee, in which it is recommended that medical officers residing outside their districts be reappointed from time to time, the letter of the Local Government Board, suggesting that such officers be appointed permanently, notwithstanding.

Mr. P. A. Taylor gave notice in the House of Commons on the 10th inst. that early next session he would ask leave to bring in a Bill to declare it inexpedient and unjust to enforce vaccination, under penalties, upon persons who regard it as unadvisable or dangerous.

The Local Government Board has called upon the Medical Superintendent of the Holborn Poor-law Infirmary, at Upper Holloway, to resign his appointment.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

The fatality of infantile summer diarrhoea showed a further increase last week, but for which the rate of urban mortality would have been exceptionally low. In twenty of the largest English towns, estimated to contain in the middle of this year seven and a half millions of persons, or nearly one-third of the entire population of England and Wales, 4741 births and 3431 deaths were registered last week. The births were 444 below, whereas the deaths exceeded by 156, the average weekly numbers during 1879; the deaths showed a further increase of 78 upon the comparatively low numbers returned in recent weeks. The annual rate of mortality per 1000, which had slowly increased in the five preceding weeks, from 18.9 to 23.3, further rose last week to 23.9. During the past five weeks of the current quarter the death-rate in these twenty towns has averaged 21.4 per 1000, against 25.2 and 17.7 in the corresponding periods of 1878 and 1879. The lowest death-rates in the twenty towns last week were 16.9 in Bradford, 18.2 in Newcastle-upon-Tyne, 18.8 in Bristol, and 19.2 in Sunderland. The rates in the other towns ranged upwards to 24.5 in Bir-

mingham, 24.8 in Brighton, 26.2 in Liverpool, 28.4 in Manchester, and 30.6 in Salford. The zymotic death-rate in Liverpool and Salford showed a considerable excess; but the high death-rate from all causes in Manchester does not appear to have been due to the same cause.

The deaths referred to the seven principal zymotic diseases in the twenty towns, which had steadily increased from 406 to 884 in the eight preceding weeks, further rose last week to 996. These included 711 from diarrhoea, 99 from scarlet fever, 80 from whooping-cough, and 50 from measles. The annual death-rate from these seven diseases averaged 6.9 per 1000 in the twenty towns; while it was but 3.5 and 3.7 in Newcastle-upon-Tyne and Bristol, it ranged upwards to 10.0 and 12.1 in Leicester and Salford. Scarlet fever was proportionally most fatal in Norwich, Sunderland, and Salford; whooping-cough in Liverpool, and measles in Leicester. No less than 12 of the 14 deaths referred to diphtheria occurred in London. Small-pox caused 2 deaths in London, but not one in any of the nineteen large provincial towns. The number of small-pox patients in the Metropolitan Asylum Hospitals, which had been 200, 198, and 178 at the end of the three preceding weeks, had further declined to 143 on Saturday last; 15 new cases were admitted to these hospitals during the week, against 22 and 16 in the two previous weeks. The Highgate Small-pox Hospital contained 7 patients on Saturday last.

The fatal cases of diarrhoea in the twenty towns, which in the seven preceding weeks had steadily increased from 51 to 577, further rose last week to 711, of which 367 occurred in London. The annual death-rate from diarrhoea averaged 4.9 per 1000 in the twenty towns; it was equal to 5.2 in London, and to 4.7 in the nineteen provincial towns. The diarrhoea death-rates ranged in the several towns from 0.9 in Sunderland, and 1.4 both in Newcastle-upon-Tyne and Oldham, to 7.3 in Brighton, 7.4 in Portsmouth, 7.6 in Leicester, and 8.1 in Salford. Diarrhoea fatality showed a decline in Brighton, but had increased in most of the other towns.

The deaths referred to diseases of the respiratory organs in London, which had been 161 and 200 in the two preceding weeks, declined again last week to 175, but exceeded the corrected weekly average by 27; 100 resulted from bronchitis, and 47 from pneumonia. The annual death-rate from diseases of this class was equal to 2.5 per 1000 in London; it was 3.9 in Liverpool.

HEALTH OF SCOTCH TOWNS.

In eight of the largest Scotch towns, having an estimated population of rather more than a million and a quarter persons, the annual death-rate averaged 19.8 per 1000 last week, against 20.6 and 18.4 in the two preceding weeks; this rate was 5.1 below the average rate in the twenty large English towns. The rates in the eight Scotch towns ranged from 13.4 and 15.6 in Dundee and Perth, to 22.1 and 38.2 in Aberdeen and Paisley. The fatal cases of the seven principal zymotic diseases in the eight towns were 125, against 107 and 117 in the two preceding weeks; they included 61 from diarrhoea, 18 from scarlet fever, 15 from whooping-cough, 15 from measles, 13 from fever, 3 from diphtheria, and not one from small-pox. The annual death-rate from these seven diseases averaged 5.0 per 1000 in the eight towns, against 6.9 in the large English towns; the excess in the English towns was entirely due to the greater fatality of infantile diarrhoea. The zymotic death-rate in the Scotch towns ranged upwards from 0.7 and 2.0 in Greenock and Aberdeen, to 8.0 and 9.6 in Leith and Paisley; the excess in Leith was mainly due to scarlet fever, and in Paisley to diarrhoea and whooping-cough. The fatal cases of diarrhoea in the eight towns, which had been 39 and 59 in the two previous weeks, further rose to 61 last week; the annual death-rate from this disease, however, did not average more than 2.5 per 1000, whereas the rate in the English towns averaged 4.9. The highest rates from diarrhoea were 3.5 in Glasgow, and 5.3 in Paisley. Eleven of the 15 fatal cases of measles occurred in Glasgow, as also 9 of the 15 deaths from whooping-cough. Of the 18 fatal cases of scarlet fever 9 were recorded in Glasgow, 5 in Edinburgh, and 4 in Leith. The 13 deaths referred to fever corresponded with the number in the previous week, and included 6 in Glasgow, 3 in Edinburgh, and 2 in Dundee. The deaths attributed to acute lung diseases (bronchitis, pleurisy, and pneumonia) were 67 in the Scotch towns last week, against 69 and 59 in the two preceding weeks; the annual death-rate from these diseases was equal to 2.7 per 1000, against 2.2 in London. The causes of

90, or 18 per cent., of the 491 deaths registered in the Scotch towns last week were uncertified; in the English towns the proportion of uncertified deaths did not exceed 2 per cent.

HEALTH OF DUBLIN.

The annual death-rate in Dublin, which had steadily declined in the eight preceding weeks from 42·5 to 28·2, rose again last week to 35·2, and was higher than it has been in any week since the middle of June. During the past five weeks of the current quarter the death-rate in the city has averaged 31·0 per 1000, against 21·9 in London, and 17·7 in Edinburgh. The deaths in Dublin included 43, or 20 per cent., which were referred to the seven principal zymotic diseases, against numbers declining from 53 to 35 in the five preceding weeks; 6 resulted from small-pox, 7 from measles, 11 from scarlet fever, 5 from whooping-cough, 5 from fever, 9 from diarrhoea, and not one from diphtheria. The annual death-rate from these seven diseases was equal to 7·1 in Dublin; it was 7·3 in London, and 5·4 in Edinburgh. The fatal cases of small-pox were somewhat less numerous than in recent weeks, but 42 have been recorded since the end of June. The deaths from scarlet fever, measles, and diarrhoea exceeded those returned in recent weeks, while those of whooping-cough and fever showed a decline. The fatal cases of diarrhoea, which had been 4 and 5 in the two previous weeks, further rose to 9 last week, but the death-rate from this disease was considerably below the average rate that prevailed in most of the large English towns.

PORTUGUESE MORTALITY STATISTICS.

Since the beginning of the year official weekly mortality statistics have been issued for Lisbon and Oporto. These weekly returns, which we believe are the first that have been issued in Portugal, are very simple in form, but they afford the means of calculating the rate of mortality prevailing in those cities. The population of Lisbon with its immediate suburbs is given as 225,152 persons, and during the first quarter of this year the deaths registered were equal to an annual rate of 30·4 persons living. For comparison with this rate it may be stated that the annual death-rate during the same period was equal to 27·3 in London, 34·9 in Paris, 25·7 in Berlin, 30·9 in Vienna, 52·0 in St. Petersburg, and 46·4 in Rome. So far as may be judged from the returns, the excess in Lisbon during the first quarter of this year was mainly due to the exceptional fatality of lung diseases. The deaths from zymotic diseases included 20 from typhoid fever and 33 from diphtheria. We regret to see that at present these returns give no information as to the birth-rate in Lisbon, or of the ages of the decedents.

HEALTH MATTERS GENERALLY AT HOME AND ABROAD.

THE HYGIENIC ASPECTS OF THE DE LESSEPS CANAL.

The proposed maritime canal across the isthmus of Panama, should the project of M. de Lesseps be carried into effect, will, according to Dr. G. Halsted Boyland of Baltimore, prove hardly less important to the hygiene than to the commerce of the districts it will traverse. The works of the canal will, it appears, drain some of the most malarious and swampy localities in the tropics; and in this way, and by the air-channel created on the surface from the junction of the two seas, we may anticipate a marked diminution of the unwholesomeness of the localities and of the conditions which favour the development of yellow fever there. Dr. Boyland has set out his argument at length in the *Baltimore Independent Practitioner* for last month, and so enlists the interests of hygienists in this second great project of M. de Lesseps for uniting two oceans.

DIPHTHERIA IN RUSSIA.

Reports from the government of Koursk state that from the 1st (13th) January to the 1st (13th) May of the present year 4607 cases of diphtheria had occurred in the government. In December, 1879, there had been 77 cases, making a total of 4686 cases from the beginning of the outbreak, of which 1307 had been fatal. The disease had chiefly prevailed in the southern and south-eastern districts of the government, the northern districts having suffered only slightly. The Red Cross Society, by its indefatigable activity, had helped greatly to arrest the ravages of the malady.

From the 1st (13th) May to the 1st (13th) July of the pre-

sent year 247 villages of the government of Poltava had been infected with diphtheria. On the 1st (13th) May there were 125 persons ill of the disease, and in the course of the month 859 cases occurred, of which 301 ended fatally. The sanitary detachments engaged in combating the epidemic had experienced considerable difficulty in disinfecting infected houses, and it appeared that the priests encouraged the people to resist their efforts.

FLESH FOOD *versus* CATTLE DISEASE.

The House of Commons by a large majority, on the 6th inst., supported the action of the Privy Council in the maintenance of restrictions on the importation of cattle from America. Mr. Arthur Arnold's motion for removing these restrictions was negatived, on division, by 194 to 20. The question at issue was one of considerable complexity. The restrictions increase the cost of meat to the consumer in a most undesirable manner; but if they are not maintained we have no security against the introduction among our herds of fatal epizootics, and of lessening still further an already seriously diminished stock from the ravages of these maladies. To ensure a present relief in the cost of animal food, it is argued, we should be lessening our future home resources, and our last state would be worse than our first. The logic and the prudence are, doubtless, both right; but let us hope some intermediate method may be discovered by which logic and prudence on the one hand, and the food wants of the community on the other, may, if not fully reconciled, be brought into closer approximation.

A Committee appointed by the Minister for Home Affairs to regulate the prisons of Russia has reported upon the necessity of organising a system of statistics applicable to prisons, no statistics having hitherto existed with regard to them. The Committee draws a distinction between the medical and sanitary statistics of prisons and prisoners, the former being prepared solely to show the medical history and incidence of the different diseases which may occur, and as they affect individual prisoners; the latter having for object to show the relations of these diseases to the prison community as a whole, and to the conditions under which they arise. The Committee recommends that in future the medical officers of prisons shall be instructed to occupy themselves specially with the preparation of sanitary statistics in place of medical statistics—in other words, that the records they keep shall have reference not only to the clinical nature, the medical treatment of cases and the results, but to the probable causes of the sickness, and their removal.

A report was presented to the London School Board on the 5th inst. on an examination of girls in board schools for certain prizes offered by the National Health Society. The report contained abundant illustrations to show that a reasonable acquaintance with writing, spelling, and understanding English had not been considered a necessary preliminary for the scholars entering upon the rudimentary study of animal-physiology and becoming candidates for the prizes to be given for proficiency in the subject.

The Vaccination Act, 1880 (India), received the assent of His Excellency the Governor-General on the 9th July, 1880, and was promulgated for general information in the *Gazette of India* for July 10th, 1880. We reserve an analysis of this Act for another occasion.

The purity of the water-supply of Plympton continues to be an undecided question with the authorities of the Union. Analysts and sanitary inspectors are still at variance on the subject, and report different results.

A hospital for infectious diseases, built upon a site given by the Grand Duchess Catherine Michailovna, was opened at Oranienbaum, in presence of her imperial highness, on the 25th ult.

A HERBALIST and his wife, of Crewkerne, Somersetshire, were tried and convicted at the Central Criminal Court on the 6th inst. for murder in an attempt to procure abortion. The case was removed by writ of *certiorari* from the Somersetshire Assizes. The jury recommended the prisoners to mercy. A case of the same kind was tried at the Stafford Assizes on the 4th inst. In this case also the prisoner was found guilty of murder and sentenced to death.

MEETING OF THE BRITISH MEDICAL ASSOCIATION AT CAMBRIDGE.

OVER four hundred members of the Association arrived in Cambridge before Tuesday evening, many of whom attended the service in King's College Chapel, after which the Bishop of Ely preached before the Association. The Senate House was well filled at 8 P.M., to hear the President's address (printed in another part of our present issue); but owing to the large size of the hall, and the rather low position of Dr. Humphry, he could not be well heard. Those who were fortunate enough to be within the reach of his voice expressed their warm appreciation of the address by frequent cheers. A cordial vote of thanks to the President for his address was moved by Dr. Husband, of York, seconded by Professor Lister, and carried by acclamation. A similar compliment was then paid to the retiring President, Dr. O'Connor, of Cork, who was elected a Vice-President of the Association. Dr. A. Carpenter, President of the Council, then moved the adoption of the Report of the Council of the Association, but was neither allowed to read the Report nor make any remarks thereon, there being an evident desire to repair to Caius as soon as possible. The Report was adopted, and then some regulations for the conduct of the annual meetings, drawn up by the Committee of Council, were proposed for adoption. Dr. Norman Kerr moved an amendment, to the effect that in future the price of the annual dinner ticket should not include any charge for intoxicating liquors. He took this step, he said, in the interests of justice and fair-play, and not from any other motive. He strongly asserted that it was unfair to tax abstainers for the potations of others. His amendment was seconded by Professor Macnaughton Jones, of Cork, and was supported by several other members. Ultimately, to meet various minor objections, the original regulations were adopted, and Dr. Kerr's proposition was moved as an original motion, in the form of an instruction to the Council of the Association, and with the substitution of the word "wine" for "intoxicating liquors." This was carried with scarcely a dissentient vote. The Association and some of the lady visitors then adjourned to Caius Dining-hall for tea and coffee, which proved hardly large enough for the crowd that pressed in. This closed the formal proceedings for the evening; but as many of the colleges are entertaining the doctors it is too much to assert that the members of the Association then dispersed.

The reception room was at the Town Hall, the large hall being used as the general museum, where there was a good display of surgical instruments, drugs, &c., and the members were introduced to the charms of that invigorating but not intoxicating beverage *zoedone*.

Business began again at eleven on Wednesday in the Senate House with the Address in Medicine, by Dr. Bradbury (printed elsewhere), followed by the special grace for honorary degrees.

It was what is known as a "scarlet day," and the bright dresses of the ladies, and the scarlet robes of the doctors, added considerably to the effect of the scene. Precisely at 12.30 the Vice-Chancellor entered, and the Public Orator then gave a Latin oration, and presented the following gentlemen for the honorary degree of LL.B.:—Prof. Brown-Séquard, Dr. Donders, Dr. S. D. Gross, Sir William Jenner, Sir William Gull, Sir George Burrows, Mr. W. Bowman, Rev. S. Haughton, Mr. Lister, Dr. D. O'Connor, Mr. J. Simon, and Dr. Andrew Wood. The Undergraduates in the gallery maintained their reputation for warmth of their reception, and also for discernment of popular feeling, for the cheers that greeted Sir William Gull were for some time threatened to be drowned in hisses and groans, and calls for Dr. Pavy. Perhaps the most striking part of the ceremony was the ability displayed by the Public Orator, who had to make a laudatory address in good Latin to each of the graduates, which must have been no easy matter, as they were all members of one profession.

At five o'clock Mr. C. Stanford gave an organ recital on the famous instrument in Trinity College Chapel, which was not so largely attended as it deserved.

At nine o'clock the members of the Association and other visitors began to assemble at the Fitzwilliam Museum, at the invitation of the President of the Association. Dr.

Siemens undertook to light the Museum with the electric light, which gave a very brilliant effect to the gathering. In addition to the various valuable and very interesting art-collections which enrich this museum, music was provided, and many enjoyed strolling through the adjoining grounds of Peterhouse, which were very prettily illuminated.

Medicine Section.

The address on Medicine, on Wednesday (printed elsewhere), which inaugurated the proceedings in the Medical Section at the Cambridge meeting, while not pretending to a high scientific value, was one of undoubted utility. Medical science advances by many channels. It is essential that from time to time its paths and progress should be depicted. Few members of the profession have opportunity, and fewer still have leisure, to keep abreast of the fast-moving wave of knowledge, and such a summary as that which Dr. Bradbury furnished of the positions gained by the advanced guard of medical science is convenient and useful. Instruments of precision have revolutionised many branches of scientific work. They substitute the definite for the vague, the precise for the uncertain. Rough observations are confirmed and corrected, and new facts are ascertained. The microscope and, in its simple use and complex methods, the sphygmograph, the ophthalmoscope, the laryngoscope, and other instruments, have not only given us certainty where conjecture was the only guide, but they have yielded new facts in the special departments which they subserve, and have supplied most unexpected information in regard to diseases with which their use had apparently no connexion. That the position of an aneurism of the aorta could be revealed by a pulse-tracing or an inspection of the throat; that a tumour of the brain, or disease of the kidneys, could be discovered by looking into the eye, are facts which not long ago would have been received with positive incredulity. However familiar these and other observations of like character may be to the well educated members of our profession, there are not a few to whom they are still scarcely within the range of intelligent comprehension. Thus Dr. Bradbury's summary of the information which instruments of precision have furnished us, if rarely rising to an original level, and occasionally accepting somewhat uncertain facts, will still be of service to a large number of those who heard or will peruse it.

The attractions in the several sections of the Association were so far coincident in their influence as to lessen the interest of some of the discussions. In the Medical Section Dr. Bristowe supplied an able *résumé* of the facts of hysterical anaesthesia as they had come under his notice, but was unfortunately prevented, by time limitation, from entering on the still more interesting question of their nature. The scope for discussion which his address furnished was correspondingly limited, and the section was thus left in doubt of the significance to be attached to some points on which he especially insisted. The variation in the symptoms, the fact that the several sensory functions are variously affected, and that heat and cold may be felt when large surfaces are involved, and may not be felt when they affect small areas, are facts of much interest as regards the nature of the pathological change. The similarity of the anaesthesia of organic and of functional origin is a point which is of less practical than theoretical importance, for it is seldom that any difficulty of diagnosis between the two presents itself; and certainly such difficulty will rarely occur with the unfrequent choreic and diphtheritic anaesthesia, on which Dr. Bristowe laid rather too much stress. Some interesting facts, positive and negative, regarding the action of metals, were supplied by Dr. Bristowe and other speakers, especially by Dr. McCall Anderson and Dr. Hughes Bennett. Several of these cases were of a most interesting character, and demonstrated at once the truth and fallacy of the well-known statements of French observers. They comprised the alleged influence of surface applications, and illustrated the caution with which conclusions from them must be drawn. Metals were effective in some cases, ineffective in others; while in some of those in which their influence was most marked, non-metallic applications had an equal action. The rational scepticism of several speakers with regard to the connexion of the hysterical manifestations with disorders of the organs of generation found an extreme exponent in Dr. Matthews Duncan, who quoted, with expressions by word and gesture of lively contempt, the statements of M. Charcot on this subject, and doubted absolutely the reality of the alleged ovarian symptoms. Few speakers shared his

scepticism in an equal degree. Dr. Barlow believed that he had actually felt the enlarged and tender ovary even in young children, and Dr. Gowers stated that he had found marked tenderness in one ovarian region in at least half the cases of hystero-epilepsy, and pointed out the difference which national temperament probably exerts on the manifestation of hysteria, and the caution necessary in criticising by the light of English observations, the statements of observers abroad. The observations of Dr. Barlow on hysterical phenomena in young children were of much interest, although, as Dr. Gowers pointed out, the phenomena are not surprising when we consider how active the emotional condition of children is. Both he and Dr. Hughes Bennett attributed more weight to the cerebral influences in the production and removal of anæsthesia than previous speakers had ventured to assign. Dr. Paget, indeed, found more difficulty in comprehending the reappearance than the removal of anæsthesia under the influence of metallic application on the theory of expectant attention. The fact seems to be not difficult of explanation when we remember how potent an agent in the production of anæsthesia is the search for its existence. Altogether the debate was of considerable interest. It supplied abundant confirmation of the main facts, which have been brought forward by the investigations at the Salpêtrière, and it showed anew with what caution we must receive the conclusions which have been drawn too hastily from the facts observed.

Not the least interesting feature of the discussion was reserved for its close. Dr. Brown Séquard, who had been engaged elsewhere, entered after it was over, and gave, at the wish of the meeting, a description of the facts which he has ascertained relative to the transfer of anæsthesia and hyperæsthesia consequent on hemi sections of the base of the brain and spinal cord. These facts are already familiar to our readers. They suggest how large a share inhibition may play in the production of the symptoms of organic lesions, and how the mechanism of these may really be identical with that which gives rise to the symptoms of functional disturbance. A description, by the same investigator, of the results of his study of the subject of unilateral convulsions, and the similar conclusions which he has drawn from them, brought the afternoon's occupation to a close.

Surgery Section.

The proceedings were opened by a very able and eloquent address from the President of the Section, Mr. N. S. Savory, who took for his subject "Constitutional Disturbance"—a fitting prelude in every way to the important discussion on the local treatment of wounds that followed. "While Hunter, Abernethy, and Travers, and surgeons of their day held that the illness produced by local mischief was evolved through the nervous system, the knowledge more recently acquired of what is now known as 'blood-poisoning' threatens to exclude the older view altogether. In reality both these forms of constitutional disturbance occur, and although often confused, it is important to distinguish them. In all differentiated animals there is a correlation or co-ordination of parts well expressed by the term 'sympathy'; and as the grade of development rises, or as specialisation of function is further carried out, this sympathy becomes more thorough, more intimate and intense, and in man has been carried to an extreme. Although the sympathy between certain organs is greater than in others—e.g., uterus and mammæ—and may be called 'special,' there is yet no sharp line of distinction between these and others. This sympathy is established by means of the nervous system, and its maintenance is the largest and most universal office of that system. But the blood is a more universal, perhaps more subtle and more obscure, agent of sympathy. We may, therefore, well speak of constitutional disturbance through the blood, seeing in what terrible forms the affection known as blood-poisoning may present itself. In the worst examples the blood is so profoundly changed that it kills before local changes supervene, while in milder cases its effects are even more obvious by reason of the various local effects which may be found scattered over the body. But from these cases where there is some poison introduced from without we pass by insensible gradations to others in which the pyrexia, &c., are the simple result of a local inflammation. If it be true that normal nutrition and healthy blood are mutually dependent, there can of course be no disturbance of nutrition without some equivalent affection of the blood and some corresponding disturbance elsewhere. The local mischief may through the blood disturb the whole system or only

some one or two of its organs which eliminate the unhealthy matter from the blood, or upon which, for some particular reason, the burden of the mischief falls. Systemic infection in this way is far more frequent than is generally supposed, and no form of mischief can be, strictly speaking, limited to any single part. Thus, who has not been conscious, during work in the dissecting or post-mortem room, of the contact and penetration of the volatile products of decomposition? The nausea or faintness produced passes away and is forgotten, until, after many hours it may be, the peculiar odour is recognised in the excrement, the breath, or the perspiration, the different channels of elimination being employed in different individuals. The poison in this case enters the blood through the unbroken mucous membrane. But in the practice of surgery we are all familiar with instances of local sympathy through the nervous system, of pain, discomfort, or disturbance of function produced in one part by irritation of some form in another. We all remember the pain in the glans penis from vesical calculus, of pain in the testis from stone in the kidney, and of pain referred to the inside of the knee in disease of the hip; and there is often more pain in the parts affected by sympathy than in those directly disturbed. Hunter remarked that such local sympathies are often not reciprocal. Through these simpler phenomena it is not difficult to pass to the larger and more complex ones of general disturbance through the same channel. In a case of continued toothache, the pain, at first limited to the diseased tooth, spreads to adjacent ones, then to the jaw, and by and by radiates over the whole side of the face and head. Such pain as I am now referring to is often spoken of as due to 'reflex action'; it is entirely a matter between sensory nerves; it is a transference of an impression from the central extremity of one sensory nerve to the central extremity of another sensory nerve, and so gives rise to the sense of pain in the part to which that nerve is distributed. But such action may lead to disturbance in the nutrition of the part, and to further changes, which surely must be attributed to the influence of the vaso-motor or trophic nerves. The constitutional disturbance which results when the products of inflammation are bound down by a fascia or by bone, must be provoked through the nervous system; and the term constitutional irritation is not inappropriate for this kind of disturbance. The local irritation which gives rise to this is almost always accompanied by pain. Pain alone may even kill, and by itself may produce grave constitutional disturbance; more often it forms but a part of the local irritation, and pain and sympathetic disturbance are not always proportional. While both these forms of constitutional disturbance are marked by fever, inappetence, and malaise, in the more active forms of blood-poisoning, there are added rigors, with great and sudden rise of temperature, followed by profuse perspiration; and, if the case lasts long enough, congestion, inflammation, or even suppuration in various parts, and the febrile symptoms generally are more marked. In the one form the patient is rapidly destroyed, in the other he is slowly worn out. While then these two forms of disturbance can be clinically distinguished in practice, the question is not always simple, for both causes of disturbance may be at work in the same case. The local mischief which leads to the formation of unwholesome fluids will produce irritation of the nerves, and the fever will be the result of the two affections; and even when only one of these two causes is in operation at the onset it must tend sooner or later to induce the other. But although this combination necessarily occurs as a rule, no doubt, in the vast majority of cases, one of these two great forms of constitutional disturbance stands out from the other so marked in its features that practically it may be considered as the single source of mischief."

Sir HENRY THOMPSON introduced a discussion on Lithotripsy at a Single Sitting. Within fifteen months he had had fifty-six cases of stone in the bladder; six were treated by lithotomy, with one death; two by lithotripsy at several sittings, and forty-eight at one sitting, with two deaths. The results show that the new operation of Bigelow lessens the risk of lithotripsy, and leaves the bladder in a sounder condition than the old method. He summed up by saying that it was now more than ever important to settle the size and nature of the stone to be treated, and it was necessary to adopt the size of the instruments employed to the particular stone to be crushed. The use of any large and unwieldy instruments greatly adds to danger attending removal of small stones. We are not justified in removing all stones by lithotripsy; some must

be reserved for lithotomy. The new operation also is more difficult, and requires greater care than the older plan. Mr. Sympton read an account of a case of stone in the bladder with a sequestrum for its nucleus. Mr. Cadge noticed that many of Sir H. Thompson's cases had not been really removed at one sitting, but at two, and that the majority of these were small stones, the average weight being about two drachms, and he therefore doubted whether the results are better than were otherwise obtained. Before Bigelow's operation the tendency of all surgeons, he thought, including Sir H. Thompson, was to lessen the applicability of lithotripsy, and at present he was doubtful whether the new operation would enlarge the scope of lithotripsy. He was himself conscious of having made one mistake, having crushed in a case in which lithotomy was really required. The choice of operation was still the great difficulty. Bigelow's operation was quite as dangerous as the old plan. Sir H. Thompson had had two cases of severe cystitis, and he had heard of one other follow it, that he thought could have been avoided by more gentle and shorter manipulation. Mr. Wheelhouse thought that if lithotripsy was decided upon, it was better to do it at one sitting. Mr. Reginald Harrison and Mr. F. Gordon concurred. Sir H. Thompson in reply, stated that the largest instrument he had ever used was the size of No. 18; it was his hope and conviction that some day no large stones would be met with.

The discussion on the "Treatment of Wounds" was then introduced by a paper on the application of the antiseptic method in cranio-cerebral lesions, by Dr. G. YEO and Dr. FERRIER. These gentlemen used monkeys for their experiments, as most resembling man, and they were treated as nearly as possible like man. In the lower animals operations on the meninges almost always set up uncontrollable inflammation, and only one of the animals used for Dr. Ferrier's well-known experiments escaped. In the present series of experiments the scalp was purified with a solution of pure phenol (1 in 5). The spray was used in all but four cases; no drainage was employed; horsehair sutures were used. The trephine was used to inflict the injuries. Protective was found to be absolutely necessary to prevent irritation. The gauze dressings were sealed and protected by flexible collodion. In the first case operated on the dressings were displaced, and violent and fatal inflammation ensued. Of the four cases without the use of the spray, when the meninges were freely washed with phenol lotion (1 in 20), one recovered with signs of slight irritation, one died suddenly from hæmorrhage into the fourth ventricle without any signs of inflammation, and two others recovered, but there was slight superficial ulceration of the scalp. The total results were seven deaths out of twenty-six cases, but of these three were killed by cold, one of them living thirteen days, and one died from chloroform. Of the three others one died from hæmorrhage, one from shock, and only one from inflammation, and that was the one where the antiseptic method was discontinued—the first case. Of twenty-one that lived long enough for inflammation to set in, twenty, that were treated antiseptically, recovered without signs of inflammation; the one which was not thus treated died with intense encephalitis.

Mr. McVAIL followed with a paper on "Ten Years' Surgery in the Kilmarnock Infirmary." The period chosen extends from the opening of the hospital to July, 1880. The method adopted in this hospital by Dr. Borland is as follows:—No water or liquid of any kind is used; the blood is carefully mopped up with cloth rags; silk ligatures are employed; the flaps are kept open till all hæmorrhage has ceased and the surface is glazed over, they are then accurately united by silk sutures and adhesive plaster. The "dressing" consists of a single piece of lint smeared with lard, over which is a light covering and a bandage. This is generally removed in two or three days, and a little serous fluid is found. The dressing is usually renewed every two or three days, and if any antiseptic fluid is employed, great care is taken to dry the part thoroughly. In cases of compound fracture, the wound is covered over and the hæmorrhage stopped by a pad of dry lint. When there is much discharge, this dry dressing of course necessitates frequent change. Mr. McVail first compared Mr. Borland's results with those of Dr. Cameron, in the Royal Glasgow Infirmary.

In 4 years, ending December, 1878, 50 deaths in 1706 cases : 2.9 per cent. (Cameron.)

In 10½ years, ending July, 1880, 33 deaths in 1429 cases : 2.3 per cent. (Borland.)

In 2 years, ending December, 1878, 23 deaths in 878 cases : 2.6 per cent. (Cameron.)

In 4½ years, ending July, 1880, 9 deaths in 828 cases : 1.08 per cent. (Borland.)

In 1 year, ending December, 1878, 9 deaths in 505 cases : 1.79 per cent. (Cameron.)

In 2½ years, ending July, 1880, 0 deaths in 421 cases : 0 per cent. (Borland.)

Taking now the results of five years and three-quarters of Lister's practice in the Edinburgh Infirmary after the introduction of the spray, it appeared that in 33 cases of compound fractures and 72 severe injuries there were 4 deaths, while Borland had 28 major compound fractures without a death, and 4 deaths in 145 severe injuries. In primary major amputations Lister's and Borland's mortality were nearly alike; in the secondary major amputations Lister's mortality was 7.8, which, excluding cases unsuited for operation, was reduced to 4.8. Borland's was 3.7. In other operations Lister's was 3.9, Borland's 1.2. Borland had treated 181 cases of ulcer without a death, and the wonderful freedom from septic influence exhibited by ulcers was surely opposed to the germ theory. In all the groups of cases which could be compared, Borland's results were superior to those obtained by Lister. There had been a mortality of .3 per cent. from so-called hospital disease, one case of erysipelas, which did not spread to any other patient, one of pyæmia, and one of doubtful nature, while Lister had a percentage of .7 in 845 cases.

Professor LISTER, after replying to one or two criticisms of Mr. McVail, went on to remark that every good surgeon is an antiseptic surgeon, and that all the recent improvements in surgery had been improvements in antiseptic surgery, such as the frequent changing of dressings and poultices, drainage, dependent openings, the open treatment of wounds, pure ventilation, and even the judicious selection of cases, as a failure in the emunctories implies a difficulty in getting rid of septic material. But it is only lately that surgeons have aimed at asepsis or the total exclusion of septic elements. The difference between a simple and compound fracture was the best of all examples of the great importance of asepsis. It was really marvellous that the system has such a power of getting rid of septic elements, for they abound at the orifice of any gland in the body. Professor Lister then detailed the results of some experiments performed on August 4th, 1880. He drew from the jugular vein of an ox just killed some blood into a bottle, purified by heat, and from this charged twenty-four 2-oz. bottles similarly purified, and sealed them with cotton-wool caps; the operation was conducted antiseptically. They were all kept at a temperature of 98.5° F. With six of these bottles nothing else was done, and on opening one of these on August 11th, no change was perceptible in the blood, which had simply an odour of the cowhouse. On August 7th he happened to have an extremely putrid lipoma, and he dipped one end of a fine wire into its juice and then touched the serum in one of these same six bottles with the point of wire, quickly closing the bottle again. Next day there was a great alteration in its appearance, and in two days it was very offensive with swarms of bacteria, both granules and bacilli. These results showed that blood does not spontaneously putrefy, and that putrefaction is a fermentation. In the other eighteen bottles ordinary tap water was introduced: into twelve before coagulation had taken place, and into the other six after that event. The following table will facilitate reference:—

Amount of water introduced.	Bottles.			
	Before coagulation.		After coagulation.	
1 m. ...	A.	B.	...	C.
2 „ ...	D.	E.	...	F.
4 „ ...	G.	H.	...	I.
8 „ ...	K.	L.	...	M.
16 „ ...	N.	O.	...	P.
32 „ ...	Q.	R.	...	S.

Taking the latter first, after two days bottle S showed changes in the serum, which was crimson and full of minute very delicate, long bacteria, in pairs, and dense clumps, but there was no odour beyond that of the cowhouse. Two days later still, C was unchanged; no organisms. F, serum dull crimson colour, roast beef-like smell, bacteria of different kinds in it. I, no alteration in appearance, no smell, no organisms. M, pale brown serum, no abnormal odour, a very delicate branching fungus found. P, serum smelt like

mouse's urine; very delicate bacilli. These results were quite unexpected, for it is difficult to get even one-hundredth part of a drop of water free from organisms. They show that blood serum is not a favourable field for the growth of these organisms. There may be organisms present without any smell, as these experiments show; indeed putrefaction may even destroy very deadly organisms. Septicity must, therefore, include other than putrefactive changes. In the other bottles none, save Q and R, showed any change, nor were organisms present in them. Here, then, we find that organisms introduced into blood before coagulation are hindered by that blood from developing, and so septic matter introduced, mixing with the blood in a recent wound, is far less likely to do harm than if mixed with the serum, which soaks through a dressing. The coagulated blood can protect itself. Bacteria also cannot develop in concentrated solutions of albumen, and the dry dressing is therefore antiseptic, but I believe that the use of a chemical antiseptic agent is a better means of obtaining the same end. At any rate I would urge every surgeon to use some external antiseptic dressing. What form it should take must be a matter of individual conscience. The blood clot must be preserved, for if undisturbed it behaves like a healthy tissue, while if disturbed it excites putrefaction in its vicinity. A still better plan, however, is to keep the septic organisms out altogether, and not trust simply to preventing their development; the more perfectly I keep them out the more successful my practice becomes. In regard to the spray, which is the one drawback to the so-called antiseptic method, I think there is evidence that it is effectual. In empyema, for instance, without it the germ-laden air continually passing in and out of the pleura must excite putrefaction, but when the spray is used we find no such result, and the discharge becomes serous and gradually ceases. Chiene's experiments again show its utility, and my own conviction about it is such that I cannot omit it. I have now one further point to allude to. I lately removed a loose cartilage from the knee-joint of a man thirty years of age, and introduced a drainage-tube. Next day there was great pain, fever, and then rigor. In two days there was suppuration in the joint and abscesses in the vicinity; but there was no smell in the pus. I opened the joint on the opposite side, put in another tube, and ultimately the joint was saved, although the abscesses around it are not yet quite got rid of. On examining the pus I found an organism like the bacterium lactis, and Dr. Chiene found that he could not cultivate it in either meat or cucumber infusion. Here was evidently a result due to some oversight. And after some consideration I believe I solved the problem. When the drainage-tube is lifted out of the antiseptic fluid, it is lifted into common or pure air, and it is easy to see how organisms could be thus introduced into a wound through the interior of the tube. That this does not more constantly happen is due to the holes in the tube allowing the spray to get in, and to the flow of fluid through the tube when it is first introduced pushing out the air in the tube. To obviate this source of danger, lift the tube out into the spray, or hold it lengthwise in the spray, to cleanse its interior. I have often been struck with the fact that the typical results of antiseptic treatment have not been met with so uniformly since the introduction of drainage-tubes; and, at any rate, since I have given attention to this point, I have had more success in my practice.

Dr. BASTIAN.—As Mr. Lister bases his treatment on the germ theory of disease, one point in reference to that demands prompt settlement, and that is whether there are or are not organisms or germs pre-existing in healthy tissues or fluids. Lister says "No." The most recent evidence on this point is that of Chiene, who removed an organ of a recently-killed animal and placed it in some sterile infusion of cucumber, using, of course, full antiseptic precautions. The fluid remained without contamination, and there were no organisms in the tissues. I should like to know more on this point, and I should wish to challenge Mr. Lister to allow me to take part in such an experiment, and to examine the tissue myself to see if organisms are not present after some days. If organisms were to be found their presence could be explained by stating that they pre-existed, or that they developed after death. I cannot conduct the experiments alone, as if I found the organisms it would be attributed to my want of skill in the antiseptic details, but nothing would give me greater pleasure than joining Mr. Lister in such a research.

Mr. DARBY.—I question this germ theory of disease, for we live among germs, and every breath of air we draw is laden with them. Again, there is no fair analogy between the dead tissues of Lister's experiments and the living tissues treated by the surgeon. Although he had had charge of a hospital of 400 beds in Ireland, where the poor use dressings of rancid lard and cowdung, he had never seen a case of septicaemia, and did not believe there was such a thing. Putrid blood does not circulate in the living body.

Mr. ERICHSEN.—The treatment described to-day by Mr. McVail is that uniformly adopted by Lister, and with the best possible results, and I know none preferable to it, especially when the surgeon is removed from centres where every resource is at hand. Primary adhesion, Sir, is not exactly a modern invention, but men educated within the last ten years express the utmost astonishment at hearing it spoken of as a common occurrence years ago. In truth, all we know of that process we owe to John Hunter. When, however, antiseptics were introduced surgeons, from a desire to save their patients all pain, came to put up their wounds in the operating theatre, and the serum which is necessarily poured out accumulated in the wounds, sometimes decomposed, and often led to ill results. We owe much to Lister for the introduction of antiseptic surgery, though I was astonished to hear everything, even the proper selection of cases, spoken of as a detail of antiseptic surgery. As I understand it there are three principles of antiseptic surgery. 1. The first is the use of the spray to prevent the intrusion of germs during the infliction of a wound. Mr. McVail's statistics show that this is not necessary, wounds may be left open for hours, and then when brought together will close without any pus being formed; in harelip, cleft palate, and cataract we constantly see wounds so uniting although especially subject to adverse influences. 2. The second principle is the covering in of the wound to filter the air, in the form of the dry dressing—masses of lint or cotton-wool—it has given me most excellent results. But are the germs likely to do more harm? In the operation for fistula in ano, and in lithotomy antiseptics cannot be used, and who has seen mischief arise from septic influence? What we see in these cases is altogether inconsistent with our dread of the intrusion of germs into healing wounds. 3. The third principle is one that I consider all-important—it is drainage, the keystone of all treatment. Chassaignac's invention is the greatest advance in the treatment of wounds made in the present century. There are two evils, however, connected with antiseptic surgery. One was suggested afresh to mind by your very able and eloquent address: I think it has a too great tendency to narrow men's attention to local treatment to the exclusion of the due consideration of the constitutional condition; and I think also that it has tended to the hygienic improvement of hospitals, for it remedies the evils of badly-built and arranged hospitals when our true course would be to construct and manage them in accordance with our advancing knowledge of hygienic laws.

Professor MACLEOD (Glasgow) thoroughly believed in Lister's treatment, and acted in the faith of the germ theory, as any one who wished to carry out the practice must. Having seen the practice in the Glasgow hospitals before and after the introduction of Listerism, he must bear emphatic testimony to the great change for good that had taken place. But antiseptics cannot do everything, and some of the improved result is due to improved methods of arrest of hæmorrhage, drainage, rest, and more careful attention to many local and constitutional details. For the arrest of hæmorrhage he preferred well-prepared catgut, or carbolised silk cut short, and could not wish for anything better than these. It was very important to see that drainage was complete, and by gravitation, and it was better to have several short tubes than one large one, so placed that when in bed the wound drained. Since 1874 he had had under his care in the Western Infirmary 729 cases of injuries and operations (excluding lesser ones) with a mortality of 3·3 per cent. All the cases were treated antiseptically.

Mr. LUND.—Putrefaction is impossible without bacteria, and it is putrefaction we have to dread. Every case of septic poisoning is the result of auto-inoculation, and we ought for this reason to centre all our attention upon the local treatment.

Mr. JOHN WOOD.—The power of the blood to resist putrefaction depends upon the vital power of the blood, and it is to this that we have to look in the large number of our cases. But the class of persons who make the difference between a percentage of 3 and 7 of deaths are those requiring [the

very greatest skill of the surgeon; and here the antiseptic treatment is useful in saving a certain number of people who would otherwise succumb. It also extends the aim, scope, and value of surgery. There are operations now justifiable which are too risky to be otherwise undertaken, though I by no means intend to justify many of the recent developments of operative surgery; for a single case of death after an avoidable operation goes far to neutralise the benefit of 100 successes. I myself have done about 300 cases of the radical cure of hernia, and about 50 under antiseptics, and among these have not seen a bad symptom even; but then I never operate unless the patient is otherwise healthy.

Mr. LISTER replied, that the good results obtained in the operation for harelip were undoubtedly due to the antiseptic action of the living tissues. He should be sorry to think that antiseptic treatment led to neglect of constitutional treatment, or of hospital hygiene, but it certainly improved the latter in one important manner, for it now was no longer necessary to have all the windows of a ward open through the winter, and to kill a few patients by pneumonia and pleurisy to save the many from pyæmia. After much careful work he hoped he had at last discovered a way of preparing catgut, which ensured its not softening too soon, or remaining rigid too long; but until he was certain that this was so, he should not publish the method.

Pathology Section.

The Pathological Section held its meetings in the new museum buildings, and there was in connexion with it an exhibition of pathological drawings and specimens, and of microscopic specimens. Amongst the latter were especially noticeable several beautiful series of specimens by Dr. D. J. Hamilton, of Edinburgh, illustrating his researches on the nature of phthisis and tuberculosis of the lungs, of which an account was given in a paper before the section, and also of tumours and cirrhosis of the liver, &c.; Dr. Dreschfeld, of Manchester, had some specimens of fibroid phthisis; Dr. Leech, of Manchester, a series of sections of glomerular nephritis; Mr. Frederic Eve showed the gradual transition of ichthyosis into epithelioma, and there were various other preparations and sections. There was an excellent series of micro-photographs of the brain and spinal cord, by Dr. Deecke, of New York, and of the blood by Dr. Woodward, of Washington, U.S.A., both shown by Dr. Clifford Mercer; and Dr. Greenfield exhibited micro-photographs of anthrax organisms. Of bone diseases there were series of preparations of artificial necrosis, contributed by Professor Busch, and diseased bones from syphilis by Mr. Jonathan Hutchinson, and Dr. Barlow. On the whole, the exhibition of specimens, though not large, was very select and interesting.

The section began its work with the consideration of the influence of the injuries and morbid conditions of nerves on nutrition. The attendance was very good considering the somewhat abstruse and difficult nature of the subject. The discussion was opened by Mr. Jonathan Hutchinson, who took a somewhat negative side of the question, generally opposed to the idea of the trophic function of nerves. Mr. Hutchinson illustrated his views from a large number of diagrams. Commencing by drawing attention to the fact that the nervous system regulates the supply of blood and nutriment, he suggested that the changes due to the derangement of these must always be eliminated before assuming a direct action of the nervous system on morbid change. Moreover, it must be allowed that the sensory nerves may act as indirect exciters, stimuli conveyed by them causing reflex circulatory changes limited to their area of distribution. As illustration of the cases which do not justify the conclusion drawn from them, he cited Mr. Hilton's well-known case in which gangrene in the parts supplied by the ulnar nerve occurred in a limb, when arterial supply was also occluded. Spasm of the vaso-motor nerve would therefore be an added cause, not the sole cause, and this would form no evidence of direct action in the nutrition. In the same way some cases of so-called *digiti mortui*, and similar gangrene might be induced by irritation conveyed from the sensory to the vaso-motor nerves in a reflex manner. In other similar ways fallacies might occur from not recognising the part played by similar reflex excitation. Another fallacy was that of not recognising simple local causes.

Ophthalmology Section.

In the Ophthalmological Section the morning was spent in testing the perception of colour of numerous members of the

Association, and at least one case of deficient perceptivity was noted.

At two o'clock the proper business of the Section was commenced by Mr. Bowman, who stated that he had prepared himself to make a few observations of an introductory nature in regard to Glaucoma, which was the subject that had been selected for discussion, but finding that there were several papers on the subject by different gentlemen well qualified to deal with it, he thought he should do better to postpone what he had to say till after those papers had been read. He accordingly called on Mr. Priestley Smith, who had a paper on the Pathology of Primary Glaucoma. Mr. Smith was understood to say (though in the after debate he rose several times to correct misrepresentations) that in primary glaucoma there was a diminution of distance between the cornea and the lens, and that this was due to an enlargement of the lens, an enlargement that progressed with the advance of age; so that at that period at which glaucoma was most common, the increased size of the lens (photographs and specimens of which were exhibited) the margin of the iris was pressed against the cornea, and the communication between the aqueous and the canal of Schlemm—the drainage tube of the eye—was practically shut off. Dr. Brailey, in a very excellent speech, gave the results of his numerous dissections and examinations, all tending to show that the cause of glaucoma is some disturbance in the balance of pressure between the aqueous and the vitreous, which again is referable to some obstruction of the drainage system of the eye. From the pathology, the discussion wandered into the treatment of the disease, and Mr. Walker, of Liverpool, advanced the filtration theory as an explanation of the good effects of iridectomy, after which speeches were made by Mr. Cowell, Mr. Vose Solomon, and Dr. Argyll Robertson, each speaker advocating his own special method of operative procedure. Professor Donders, who had been a patient listener, was then called upon by the President, but confessed his inability to deal with the subject. Many more facts he contended were required before any conclusions of a satisfactory nature could be drawn in regard to the nature of glaucoma. As to Priestley Smith's suggestion of the increase in the size of the lens, he thought the lens ought to be weighed as well as measured, and he made a valuable suggestion to the effect that an injection of the vessels should be, if possible, obtained. The President then made some remarks, showing clearly enough that the pathology of glaucoma has still to be worked out.

Mr. Couper then read a paper on rapid Dilatation of the Lachrymal and Nasal Ducts, by means of large Probes, a method which was endorsed by several subsequent speakers. We noticed M. Landolt, M. Warlomont, Mr. Critchett, Dr. Wolfe, and many English ophthalmologists. The meeting was exceedingly well attended. M. Landolt exhibited a new speculum.

The third general meeting of the Association was held at ten o'clock on Thursday morning in the Senate House. Various reports were adopted. The place of meeting for next year was named but not settled; Brighton was mentioned. It was announced that the Government had decided to bring in a Bill to institute one compulsory qualification for the United Kingdom. Mr. Holmes delivered the Address in Surgery, which was well received. A vote of thanks to the orator was proposed by Sir H. Thompson, seconded by Mr. Cadge. The President then handed the Medal of the Association, presented for conspicuous merit, to Dr. Acland to convey to Dr. W. Farr. In well-chosen words he expressed the regret of all present at the enforced absence of Dr. Farr, and the high esteem in which he is held by the profession, and the great value of his work to England and the whole world. About 800 members took part in the proceedings of this day.

THE SERVICES.

LIST OF MEDICAL OFFICERS SERVING IN AFGHANISTAN.

OUR correspondent with the army in Cabul has furnished us with a list of medical officers of the Army at present employed with the army in Northern Afghanistan. In the present state of affairs this is of considerable interest. At the time of our correspondent's despatch, the medical details of the Kandahar division were not complete, but we hope to receive them by an early mail.

Northern Afghanistan Field Force.

Principal Medical Officer—Deputy Surgeon-General A. Smith, C.B.

1st Division (Sir Frederick Roberts).

Deputy Surgeon-General—H. B. Hassard.

Surg.-Major W. F. Rutledge in medical charge G-3 R.A.

Surgeon E. H. Févre " 6-8 R.A.

Surg.-Major R. Lewer " 9th Lancers.

" C. A. Atkins " } 72nd

" G. T. Langridge " } Highlanders.

" " " " } 92nd

" S. B. Roe " } Highlanders.

" E. Hopkins " }

" W. F. Bennett " }

Surgeon J. F. Williamson } Field Hospitals.

" H. Cotton " }

" H. C. Kirkpatrick " }

2nd Division (General Ross, C.B.)

Deputy Surgeon-General J. A. Hanbury.

Surg.-Major E. Footner in medical charge 6-11 R.A.

Surgeon J. J. Greene " 12-9 R.A.

" P. J. Macquaid " 67th Regiment.

Surg.-Major J. Ekin " 2-9th Regiment.

" J. Fleming " }

" G. Evatt " }

" G. W. MacNalty " } Field Hospitals.

Surgeon P. Connolly " }

" J. Brodie " }

3rd Division (General Hills, V.C., C.B.)

Brigade-Surgeon—R. W. Meadows.

Surgeon A. W. Carleton in medical charge A-B. R.H.A.

" F. W. Trevor " G-4 R.A.

Surgeon-Major S. G. White " 11-11 R.A.

Surgeon S. H. Carter " 60th Rifles.

Surgeon-Major C. W. Watling " 59th Regt.

Surgeon-Major W. S. Whylock " }

" E. C. Markey " } Field Hospital.

" J. H. Moore " }

Surgeon A. W. Browne " }

Kuram Force.

Principal Medical Officer—Deputy Surgeon-General A. J. Dale, Indian Medical Service.

Surg.-Major W. O'Halloran in medical charge E-3 R.A.

" T. W. Patterson " 1-8 R.A.

Surgeon R. H. Quill " C-4 R.A.

Surgeon-Major R. Jackson " 2-8 Regt.

" W. M. Harman " 85th Regt.

Surgeon P. G. Jones " Detachment

" " " Rifle Brigade.

Surgeon-Major J. Wright " }

" J. J. O'Reilly " }

Surgeon W. Donovan " } Field Hospital.

" J. C. Dorman " }

" J. Boulger " }

" P. H. Johnston " }

Khyber Line Force (General R. Bright, C.B.)

Deputy Surgeon-General A. M. Tippetts.

Surg.-Major T. Oughton in medical charge 11-9 R.A.

" W. J. Rainsford " C-3 R.A.

" W. W. Kenny " L-5 R.A.

" Major R. W. Davies " 6th Drag. Grds.

" W. Morris " 1-5th Fusiliers.

" R. C. Eaton " 1-18th Regt.

" D. A. S. Thorburn " 2-14th "

" W. F. Burnett " 1-25th "

" W. Creyk " 51st "

Brigade-Surgeon A. Guthrie " }

Surg.-Major A. G. Bartley " }

" J. W. Loughheed " } Field Hospitals.

" J. A. MacCracken " }

Surgeon J. A. Goomley " }

" J. Pedlow " }

" F. A. Davey " }

INDIAN MEDICAL SERVICES.

We are glad to learn that the Marquis of Ripon intends to institute an inquiry into the grievances of the Indian Medical Service. Whatever difference of opinion there

may be as to the manner in which the abolition of the dual administrative staff has been effected, there can be none as to the existence of real grievances in the scale of pensions for the medical officers, the relative rank of the juniors, the niggardly share in the distribution of honours, and the system of allowing officers to decline promotion for the purpose of retaining lucrative appointments. The Marquis of Ripon is practically well qualified to adjudicate upon such questions from his long experience in the War Office, and his knowledge of the requirements of the Army Medical Service. We entertain strong hopes that he will be able to overcome some of the difficulties which have arisen in the working of the new system, and to place the Indian Medical Service on a more satisfactory footing. Of one thing we are well assured, that he will endeavour to do justice to the two medical departments without favour or partiality.

INSPECTION OF THE ARMY HOSPITAL CORPS AT ALDERSHOT.

Sir William Muir, Director-General of the Army Medical Department, accompanied by Surgeon-General William Munro, C.B., and Captain Pringle, A.H.C., made an official inspection of the Army Hospital Corps Depot and Training School, on Friday last. The depot numbered 250 strong, and was drawn up under the command of Surgeon-Major Sandford Moore. The class of young medical officers, who have lately passed through Netley, and who have been for the last two months undergoing instruction in ambulance work, were also inspected, and put through "stretcher drill" by the instructors. After the inspection, the Director-General and his staff were entertained at luncheon by Surgeon-General Shelton and the officers of the Army Medical Department, in their new messroom in V Lines.

DEATH OF SURGEON C. H. MURRAY, H.M. INDIAN MEDICAL SERVICE.

We regret to announce the death, on the 10th July, at Peshawur, East Indies, of Surgeon Charles Herbert Murray, M.D., of the Bengal Medical Service. Dr. Murray obtained his commission as recently as March in last year, and has fallen a victim, at the early age of twenty-five, to the deadly climate of the Peshawur Valley.

ADMIRALTY.—Deputy Inspector-General of Hospitals and Fleets Charles MacShane has been placed on the retired list from the 7th inst., with the rank of retired Inspector-General of Hospitals and Fleets. Staff-Surgeon Fleetwood Bucke has been appointed to the *Kingfisher*; Surgeons J. Dudley to the *Iron Duke*, for Yokohama, sick quarters; A. MacKinlay to the *Mosquito*; J. O'Callaghan to the *Warrior*; William Putsey to the *Alexandra*; J. T. W. S. Kellard to the *Himalaya*; Robert Bedford to the *Duke of Wellington*, for Haslar Hospital.

Dr. Eaton, of the 16th Native Infantry, while proceeding on duty with a detachment of the Scinde Horse was fired at, on the 6th July, by a party of Pathans, near the Chuppar Mountains, and had his horse killed under him.

PARIS.

(From our own Correspondent.)

THE proposal which was mentioned in THE LANCET of February 28th, that the State should make provision for the wives and families of medical men who shall die from disease contracted in the exercise of their profession, has not met with the approval of the present Minister of the Interior. After the Commission appointed by the Chamber of Deputies to examine into the question had reported in its favour, the matter remained with the minister, who has now written a letter to the president of the Commission of petitions which embodies his views. This document is too long to transcribe *in extenso*, but the principal arguments against the measure are directed against the parallel which the petitioners sought to institute, between the physician who loses his life by disease communicated to him, from his patients, and the soldier who dies for his country on the field of battle. "Medical men," says M. Constans, "are not servants of the State like soldiers, and consequently the

State owes them no pecuniary reward. It is a principle of law that pensions are only due to those citizens who have devoted their lives to the service of the nation, and in an exclusively public interest. If pensions were to be awarded to the widows of medical men and gratuitous instruction to their children, they could not be refused to nurses and hospital attendants; and, indeed, there would be no reason why the survivors of any person whose life had been sacrificed in the pursuit of a useful profession should not claim State aid on the same grounds. The exercise of medicine," continues the minister, "is generally lucrative (!), but like all others it has its dangers. It is the business of those who are interested to guard against the possibility of accident by assurance." But whilst the right of the medical profession to State aid is denied, it is admitted that it has a serious claim upon the benevolence of the State. M. Constans points out that his department has often relieved the necessities, and that the Minister of Public Instruction always looks favourably upon applications for bursaries when coming from the children of deceased medical men. The letter terminates with a recommendation that the Ministers of Agriculture and of Finance be consulted by the Commission.

The Academic Council of the University of Montpellier has given its decision in the case of M. Amagat, the *agrégé* who was the instigator of the recent disturbance in the Faculty of Medicine there. By twenty-three votes against one the following judgment was pronounced:—The Academic Council, blaming severely M. Amagat, decides that he shall be removed from the post of *agrégé* of the Faculty of Montpellier; he will, consequently, be struck off the list of *agrégés* of the said faculty; decides, moreover, that he be allowed to retain the title and emoluments of an *agrégé*, and that, as such, he shall be left at the disposition of the minister." It is most likely that M. Amagat will be appointed to a similar position in another university. The secrecy observed by MM. Pasteur and Toussaint, with regard to their processes for communicating modified diseases to fowls and cattle, to protect them respectively against cholera and charbon, has created great dissatisfaction in scientific circles; and some critics say that MM. Pasteur and Toussaint have been premature in publishing their "marvellous, mysterious, and miraculous results." At the last meeting of the Academy of Medicine, M. Bouley announced that the Academy of Sciences had been authorised by the latter to open the sealed envelope which had been deposited there, and which contained an account of the method. The protective virus used by M. Toussaint for inoculating animals with a modified disease, is carbonous blood, which has been defibrinated, and then raised to the temperature of 55° Centigrade. This destroys the bacteria which it contains. This blood inoculated upon a healthy animal produces a local disease, which does not extend its manifestations beyond the lymphatic ganglia. Twelve days after inoculation the blood of the animal experimented upon is no longer favourable to the multiplication of bacteria; and in the first cases so treated three months have elapsed, and the animals still remain refractory to repeated inoculations with the most virulent virus.

A provincial practitioner, Dr. Gerlié, has related to the Academy of Medicine how he traced a case of ringworm to the shop of a barber in his village. It had been brought there by the barber's son, who went to a school at some distance where there were twenty other children with the same affection, which had probably been imported into the school by a boy whose father had cut his hair with the same clippers he used for his horses. In consequence of Dr. Gerlié's discovery the hair-cutter's shop was deserted by his customers, and its proprietor retorted by placarding abusive notices concerning the doctor about the town; which the municipal and police authorities refused to remove. These would seem to be matters of purely local interest, but Dr. Gerlié has written a brochure on the subject, which the Academy has recommended to the attention of the Minister of the Interior, and a vote of felicitations has been passed by the venerable company "to the courageous doctor who did his duty in such difficult circumstances."

At a recent meeting of the Society of Biology, MM. Bourneville and d'Olier made a communication upon the physiological action of bromide of ethyl, or hydro-bromic ether as it is called in England. This agent was administered in five cases of hysteria occurring in male subjects at Bicêtre, and in some cases at the Salpêtrière. It caused a cessation of convulsive phenomena, and in two cases a

rapid transition from "clownism" to delirium. In epilepsy, when given during the tonic period, it produced muscular resolution in a few seconds, in three instances; in other cases the duration and intensity of the convulsions seemed to diminish, and in some it had no effect whatever. Of ten epileptic patients submitted to treatment by the daily inhalation to anæsthesia of bromide of ethyl, five have been improved during the two months which the experiments have extended over; they have gained from two to eighteen pounds in weight, and the number of fits have decreased considerably; in one instance, forty-one less in June than in May, and twenty-one less in July than in June.

MEDICAL NOTES IN PARLIAMENT.

In the House of Commons on Thursday, the 5th inst., a petition was presented from Lurgan Union for alteration of the law relating to lunatics and paupers. A return, moved for by Professor Thorold Rogers, was presented, giving the number of applications made under the Medical Officers' Superannuation Act (England) to Boards of Guardians for superannuation allowances, &c.—Mr. Ritchie asked the Secretary of State for the Home Department whether his attention had been called to the case of George Lamb, who was convicted at the Thames Police Court of exposing for sale unwholesome meat and fined 2s. 6d.; and, if so, whether he has thought it necessary to ask for some explanation from the magistrate of what seems so inadequate a punishment for so serious an offence.—Sir W. V. Harcourt had made inquiry, and found that this was not a serious case. The defendant had six tins of Australian meat in his possession, which were unfit for human food, but he placed the meat aside on discovering its condition, and did not sell any of it. The magistrate was inclined to dismiss the case, but decided to impose a nominal fine, so as not to encourage carelessness in such matters.—Mr. Dawson gave notice of the following questions, to ask the Chief Secretary to the Lord Lieutenant of Ireland, whether he is aware that one gentleman, Dr. E. A. Rawson, holds the following appointments in Carlow—viz., (1) surgeon to the Militia (entailing occasional absence); (2) surgeon to County Infirmary; (3) physician to Fever Hospital; (4) physician to Workhouse; (5) consulting sanitary officer: and that, whilst holding all those appointments, he has been recently sanctioned as substitute during leave of absence, to Dr. M'Dowell, who holds the following positions:—(1) physician to the Dispensary; (2) surgeon to various Police Stations; (3) registrar of births and deaths; (4) medical officer of health; (5) public vaccinator: and whether such an arrangement meets with his approval.

On Friday, Mr. Robert Fowler asked the Under Secretary of State for Foreign Affairs, whether Her Majesty's Government have taken any steps to put an end to the interference, on the part of the Japanese Government, in the drug and chemical trades, which was the subject of a memorial, signed by several influential firms, to Lord Salisbury in August last. Sir C. Dilke said a copy of the memorial was sent to Her Majesty's *chargé d'affaires* in Japan, with instructions to take such action as might be necessary for the protection of the importers of drugs, in case there should be proper grounds for the interference of Her Majesty's Government.

On Monday, a petition was presented for the restoration of a faculty of medicine to the University of Oxford. The County Court Jurisdiction in Lunacy (Ireland) Bill was brought down from the Upper House and read a first time. In reply to Sir S. Northcote, Mr. Dodson intimated that the Vaccination Acts Amendment Bill would not be proceeded with. Later in the sitting the order of the second reading was read and discharged, and the Bill was formally withdrawn. Mr. Hopwood asked the President of the Local Government Board, by whose authority a "Note" was appended of information not ordered by this House to the Return on Mortality (General and Infant), dated the 16th day of June, 1879. Whether the Note is not misleading, as it compares the epidemic years 1838-42 with years consisting of epidemic and many non-epidemic years, and omits the years 1843, 1844, 1845, and 1846, which

were non-epidemic years altogether; and whether he will give consent to a return of deaths from small-pox for England and Wales during the years 1843, 1844, 1845, and 1846. Mr. Dodson said the Note was appended by authority of the late Registrar-General. Its object was not to mislead, but to show the average rate of mortality over the whole series of years for which the information was available. The years 1843-1846 had been omitted because the cases of death from small-pox during that period had not been classified. Mr. Corbet put a series of questions—which appeared in last week's LANCET—with reference to the superannuation of medical officers of lunatic asylums in Ireland. Mr. Forster replied, that the English Act of 1862 did fix fifteen years as the minimum period for pensioning officers of lunatic asylums in England, but it did not prescribe that after that period of service they should be entitled to pensions equal to two-thirds of their salaries. In Ireland, these officers were regarded as civil servants, and their superannuation was regulated on the principle of the Superannuation Act of 1859. They must have served forty years to become entitled to a pension equal to two-thirds of the salary. The Government were entitled to add a number of years to the service of any officer having special professional qualifications. He could not state at present that he would bring in a Bill to increase the allowances of officers of lunatic asylums in Ireland. He must have some information that the ratepayers would be willing to bear the increased cost. Perhaps the honourable member would bring in a Bill himself.—During a discussion in Committee of Supply, on convict prisons, Mr. Sullivan complained of the want of independent medical inspection, and wished the Government to revert to the old system, whereby the highest local medical authorities were engaged as medical superintendents, and were free from any control of the prison authorities. They could go in and inspect the prison when they pleased, and the results of that independent inspection were very satisfactory. But, owing to their probing too much into prison management, they were now excluded, and the health of prisons was dependent upon medical officers who were not independent. Mr. Peel and Sir R. A. Cross defended the present system, and maintained that the existing medical supervision was efficient.

On Tuesday, Mr. Forster, replying to a question by Mr. Meldon, which we have already published, said it was the fact that the medical officer of the Crossgar dispensary district, in the union of Banbridge, having, after forty years' service, applied for superannuation, on the ground of broken-down health, the guardians refused to add to the rates by granting any such retiring allowance. It certainly was a case of great hardship, but the Irish Local Government Board had no power to interfere. This question of superannuation of medical officers was one that demanded the attention of the Government, and if time could be found amidst their other pressing business he hoped it would be dealt with.—The following notices were given: Mr. Wm. Corbet, to ask the Secretary to the Treasury, with reference to the diminution of the salaries and expenses of hospitals and infirmaries in Ireland in 1879 by the large sum of £3369 1s. 3d., as shown in the abstract of an account just issued, whether he can state the names of the hospitals and infirmaries in which reductions have been made, the amount of such reductions, and the cause thereof. Mr. Wm. Corbet, to move for a return showing, in tabular form, the number of insane persons under the jurisdiction of the Court of Chancery in Ireland, where at present located, the amount annually expended on their support and maintenance, and the total annual income of each. Mr. P. A. Taylor, to move next session, "that, in the present unsettled condition of medical opinion in regard to the safety of using ordinary humanised lymph, as also of the safety, effectiveness, and practicability of the use of animal vaccine, it is, in the opinion of this House, inexpedient and unjust to enforce vaccination under penalties upon those who regard it as unadvisable or dangerous."

On Wednesday, Mr. Grantham had the following question on the paper, but owing to the absence of Lord Hartington it was deferred:—To ask the Secretary of State for India, if he will inquire of the proper authorities in India, and report to the House early next session, whether by the report of a medical board, dated September 5th, 1868, signed Surgeon-Major Peskett, Surgeons Lowdell and Condon, and Assistant-Surgeon Walsh, at Mynee Tall, Captain Chatterton was not recommended to take twelve months' leave of absence, for the purpose of returning to England to undergo an opera-

tion—viz., the division of the left tendo Achillis, on the ground that it was not safe to perform the operation in India. Whether Surgeon-Major Powell, acting as garrison surgeon in Fort William, Calcutta, did not afterwards, in April, 1869, confirm the above recommendation on the same ground. Whether the only report on which the despatch of January 5th, 1869, ordering the compulsory retirement of Captain Chatterton, was founded, and which practically alleged that he was shamming, was not that made in November or December, 1868, by Assistant-Surgeon MacDermott, who was shortly afterwards removed from the medical charge of that and other cases previously under his care. And how it was that Captain Chatterton was dismissed the army in April, 1869, on the report of an assistant surgeon, when Captain Chatterton was acting on the reports of more eminent surgeons, made both before and after the report of the assistant surgeon.

On Thursday, Mr. Pugh asked the Secretary of State for India, whether the Orders of the Governor-General of India, No. 13, of January 3rd, 1880, Military Department, and No. 150, of March 13th, 1880, Home Department, do not contravene the provisions of s. 56 of the stat. 21 and 22 Vic. c. 106, in that they alter the terms of service, and the title to pay pensions, allowances, privileges, and advantages as regards promotion of the officers of the Indian Medical Service. Whether such orders are not so far illegal and void. And, what redress it is proposed to grant to such officers of the Indian Medical Service as have already been prejudicially affected by the operation of these orders, and what steps it is proposed to take to prevent their further operation. Lord Hartington was unable to say whether the orders in general contravened the provisions of the statute. He had, however, sent a despatch to India containing a report of a deputation he received some time ago, in which the complaints on behalf of the service were fully stated, and requesting the Government of India to give him an early and full statement of their views on the subject. Captain Home asked the Secretary of State for War whether he will consider the case of Surgeons Major of Household Cavalry, who have paid for their commissions and are now, under warrants issued subsequent to their appointments, compulsorily retired at the age of fifty-five years without compensation; and whether these officers, being debarred from promotion to the rank of Deputy Surgeons General, might not be allowed to serve until they reach the age of sixty, so as to prevent their being placed in a worse position than the medical officers throughout the rest of the Army?—Mr. Childers replied that this was the first time he had heard of the existence of the purchase system amongst the medical officers of the army, and he could not undertake to recognise it. He would look into the subject of the second question, but he very much doubted whether the medical officers of the household cavalry had any claim to more favourable treatment.—Mr. Forster, replying to the question by Mr. Dawson, above printed, said Dr. Rawson held all the offices named by the hon. member; but the third, fourth, and fifth, all required the sanction of the Local Government Board. No regulation was broken by his holding all those appointments, and the duties were not more than one man could properly discharge. The appointments held by Dr. McDowell were those usually filled by dispensary medical officers. The Dispensary Committee allowed Dr. Rawson to act for him for one month from the 20th July. There was very little illness in the workhouse or in the fever hospital, the district was generally in a healthy state, and the Local Government Board, having consulted their inspector, saw no objection to the temporary arrangement proposed. The Board had received no complaint as to the manner in which the duties connected with the workhouse hospital and dispensary district had been discharged.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At a meeting of the Council on the 5th inst., the following gentlemen, having been elected Fellows at previous meetings of the Council, were admitted as such, their diplomas of Membership bearing date respectively Feb. 8th, 1837, and May 4th, 1836:—

Haward, Edwin, M.D. Edin., Harley-street.
Underhill, William Lees, L.S.A., Tipton, Staffordshire.

At the same meeting the following gentleman was elected a Fellow, his diploma of Membership bearing date Dec. 2nd, 1842:—

King, Jasper Rumbold, L.S.A., Milksham, Wilts.

The Library and Museum of the College will be closed on Wednesday, Sept. 1st, and be reopened on Friday, Oct. 1st.

[The sixth name on our list, published last week, of gentlemen admitted Members on the 30th ult., should read—"Hart, Alfred Paul, M.B. C.M. Aberd., Norwich."]

UNIVERSITY OF LONDON. — The following candidates have passed the recent First M.B. Examination:—

ENTIRE EXAMINATION.

FIRST DIVISION.

Back, Herbert Hatfield, St. Bartholomew's Hospital.
Berry, Harry Poole, Guy's Hospital.
Beverly, John Metcalfe, Owens College.
Booth, Edward Hargrave, Guy's Hospital.
Brooks, Walter Tyrrell, King's College.
Carter, Thomas Edward, St. Bartholomew's Hospital.
Collier, Joseph, Owens College.
Cooper, George Frederick, St. Thomas's Hospital.
Dingley, Edward Alfred, University College.
Ellison, John Clement, St. Bartholomew's Hospital.
Evans, Charles Silvester, St. Thomas's Hospital.
Horrocks, William Heaton, Owens College.
Jones, Charles Montague Handfield, St. Mary's Hospital.
Lister, Joseph Herbert, Guy's Hospital.
Martin, Sidney Harris Cox, B.Sc., University College.
Moline, Paul Frank, University College.
Overend, Walker, B.Sc., St. Bartholomew's Hospital.
Price, John Alfred Parry, Guy's Hospital.
Shove, Edith, London School of Medicine for Women.
Spicer, Robert Henry Scanes, B.Sc., St. Mary's and Guy's Hospitals.
Stephens, Lockhart Edward Walker, Guy's Hospital.
Thomson, St. Clair, King's College.
Tunzelmann, Edward Waldemar von, University College.
Voisey, Clement Bernard, Owens College.
Wilkinson, William Camac, B.A. Syd., University College.
Worthington, Sidney, Guy's Hospital.

SECOND DIVISION.

Adams, William Cooode, University College.
Batten, Rayner Derry, St. Bartholomew's Hospital.
Beavor, Hugh Reeve, King's College.
Berry, James, St. Bartholomew's Hospital.
Bertram, Benjamin, St. Bartholomew's Hospital.
Campbell, Harry, St. Bartholomew's Hospital.
Cook, Augustus Henry, University College.
Cunnington, Cecil William, King's College.
Davies, William Thomas Frederick, Guy's Hospital.
Day, John Roberson, University College.
Elgoud, Charles Reginald, University College.
Faulkner, Joseph, St. Bartholomew's Hospital.
Gray, John Alfred, St. Bartholomew's Hospital.
Halliburton, William Dobinson, B.Sc., University College.
Kealy, John William Gregory, King's College.
Lewers, Arthur Hamilton Nicholson, University College.
Lynam, Robert Garner, King's College.
Marsh, Nicholas Percy, St. Bartholomew's Hospital.
Nicholson, John Williams, Guy's Hospital.
Norvill, Frederic Harvey, King's College.
Parkinson, Charles Joseph, Owens College.
Pike, Charles James, University College.
Porter, Guy David, King's College.
Rabbeith, Samuel, King's College.
Scott, Bernard Charles, Middlesex Hospital.
Waugh, Henry Dunn, B.A., B.Sc., University College.
Wilson, Arthur Henry, Royal Infirmary, Liverpool.
Wood, Louis Edmund, St. Mary's Hospital.

EXCLUDING PHYSIOLOGY.

FIRST DIVISION.

Eady, George John, King's College.
Parry, Robert, Guy's Hospital.
Payne, Charles Alexander, St. Bartholomew's Hospital.

SECOND DIVISION.

Dent, Harry Lord Richards, King's College.
Fox, Robert Fortescue, London Hospital.
Richmond, Charles Ernest, Owens College.

PHYSIOLOGY ONLY.

SECOND DIVISION.

Dingley, Arthur William, University College.

APOTHECARIES' HALL. — The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on Aug. 5th:—

Bousignac, Joseph Ludovic, Trinidad, West Indies.
Eminson, T. Benjamin Franklin, Scotter, Lincolnshire.
Faithfull, Robt. Lionel, 23rd-street, New York.
Farebrother, Wm. Arthur, Winchester-street, Pimlico.
Legge, Wm. H., Queen Anne-street.
Mahomed, Arthur G. Sulman, St. Thomas's-street.
Richards, Wm. Blagdon, Picton Castle, Carmarthen.
Weston, George Edward, Bognor, Sussex.

The following gentlemen also on the same day passed their Primary Professional Examination:—

James Callaway, St. Bartholomew's Hospital; Matthew Gunning Clark, St. George's Hospital; Herbert J. Dyson, St. Mary's Hos-

pital; Edalji R. Dadachauji, Grant Medical College, Bombay; Wm. Alexander Hepburn, Aberdeen University.

At a Court Meeting of the Master, Wardens and Assistants of the Society of Apothecaries, held on the 3rd August, 1880, the following gentlemen were elected members of the Court of Examiners for the ensuing year: Dr. Robert Hunter Semple, Dr. Charles Taylor, Dr. John Randall, Dr. Joseph Samuel Lavies, Dr. John Sherwood Stocker, Henry Bullock, Esq., Dr. John Charles Thorowgood, Dr. Robert Fowler, Dr. William F. R. Burgess, Dr. Frederick John Hensley, Dr. George H. Savage, Dr. Henry Radcliffe Crocker, Thomas R. Wheeler, Esq., Secretary to the Court of Examiners.—At the same Court the following gentlemen were elected Examiners in Arts for the ensuing year: Charles Edward Armand Semple, M.B., B.A., Cantab.; Herbert William Page, M.B., M.A., Cantab.; W. Peregrine Probert, M.A., LL.D., Cantab.; Thomas R. Wheeler, Esq., Secretary to the Board of Examiners.—At the recent examination for the Prizes in Botany given annually to medical students by the Society of Apothecaries, the successful candidates were: 1st, Joseph Baldwin Nias, student of St. Bartholomew's Hospital, the Gold Medal; 2nd, Alfred Mason Vann, student of King's College, London, the Silver Medal and books.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—

At a meeting of the Court of Examiners held on the 26th ult. and following days the undermentioned obtained the diploma in Surgery of the College:—

John Leslie Barrington, Joseph Boyd, Luke Brady, James Stewart Brooke, Humphrey John Broomfield, Augustus Jas. Arthur Brown, Walter John Clarke, Jas. Nagle Cleary, Robert Cochrane, Abraham Lyndes Connellan, Edmund Corcoran, Thomas Corcoran, John Geo. Cronyn, Edmond Francis Flynn, Charles Herbert Ford, William Fottrell, Thomas Mark Gallaber, Fitzgerald Isdell, James Alfred Johnston, Thomas Samuel Lacey, Francis Joseph Lambkin, John Lilly Lane, Peter Edmund Lemass, William Cuthbert Lucas, Saml. Foster Longhead, John Low, Jas. Patrick Mackin, Patrick Andrew M'Dermott, John Barry Moylan, George Cathcart Monray, Richd. A DRUGGIST of Broadway, Deptford, has been fined £5 and £1 costs for having mixed with tincture of quinine certain ingredients so as to injuriously affect the quality or potency of the drug.

THE returns of the Inspectors of Mines show that out of 18,795 persons employed about metalliferous mines 2193 are women and girls, and 317 boys whose ages range between eight and thirteen years.

Medical Appointments.

Intimations for this column must be sent DIRECT to the Office of THE LANCET before 9 o'clock on Thursday Morning, at the latest.

BARTLETT, J. H., L.R.C.P. Ed., L.F.P.S.G., has been appointed Medical Officer to the Porlock District of the Wilton Union.
BERKART, Dr. J. B. (late Assistant-Physician), has been appointed Physician to the City of London Hospital for Diseases of the Chest, Victoria-park, vice Dr. S. Ward, deceased.
BOVILL, Mr., has been appointed House-Surgeon at Guy's Hospital.
BRICKWELL, B. A., M.R.C.S.E., L.S.A.L., has been reappointed Medical Officer of Health for the Amersham Union. £100 per annum.
BROWN, W. P., L.R.C.P. Ed., L.R.C.S. Ed., L.S.A.L., has been appointed House-Physician to the Bradford Infirmary, vice Willmot, resigned.
BULLOCK, J. E., M.D., has been appointed Resident Physician to the Bishop's Down-grove Spa and Hydropathic Sanatorium, Tunbridge Wells.
CALCOTT, G. W. B., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer to the Barnwell and Benefield Districts of the Orsett Union.
CROOK, Mr. J. S., has been appointed House-Surgeon at Guy's Hospital.
CROSSLEY, J. P., L.R.C.P. Ed., L.F.P.S.G., has been appointed Medical Officer to the Workhouse of the Sunderland Union, vice Foote, resigned.
DAVIS, R. T., L.R.C.P. Ed., L.F.P.S.G., has been appointed Medical Officer to the Bonvilstone District of the Cardiff Union.
DENT, C., F.R.C.S.E., has been appointed Surgeon to the Belgrave Hospital for Children, vice Stirling, resigned.
ERSKINE, J., M.D., L.R.C.S.I., has been appointed Medical Officer to the South-West District of the Parish of St. Luke's, Chelsea.
FOSTER, W., B.A., M.R.C.S.E., has been appointed Dispensary Surgeon at the Bradford Infirmary, vice Brown, resigned.
HAY, W. A. E., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer to the Cross Keys Friendly Society, Bridport.
HEATH, R. E., M.D., has been appointed Honorary Surgeon to the Torbay Hospital, Torquay, vice Pollard, resigned.

JOHNSTONE, J. C., M.B., C.M., has been appointed Assistant-Physician to the Royal Edinburgh Asylum, Morningside.

KIDD, P., M.A., M.B., M.R.C.P.L. (late House-Physician and Demonstrator of Practical Physiology at St. Bartholomew's Hospital), has been appointed Assistant-Physician to the City of London Hospital for Diseases of the Chest, Victoria-park, vice Dr. Berkart, promoted.

KIDD, P. H., M.B., C.M., has been appointed Junior House-Surgeon to the Carlisle Dispensary, vice Dr. Paterson, resigned.

LANE, Mr. W. A., has been appointed House-Physician at Guy's Hospital.

LEACH, Mr. J. C., has been appointed Public Analyst for Blandford.

LEDIARD, H. A., M.D., F.R.C.S., has been appointed Surgeon to the Cumberland Infirmary, vice Macdougall, resigned.

MORGAN, Dr. W., has been appointed Public Analyst for the County of Glamorgan.

OSBORN, S., F.R.C.S., has been appointed Honorary Surgeon to the Metropolitan Convalescent Institution at Walton-on-Thames.

PATTINSON, Mr. J., has been appointed Public Analyst for the Borough of Gateshead, vice Edger.

POLLARD, W., F.R.C.S.E., has been appointed Consulting Surgeon to the Torbay Hospital, Torquay.

RAKE, Mr. B. N., has been appointed House-Physician at Guy's Hospital.

RUDDIN, G. M. A., L.K.Q.C.P.I., L.R.C.S.I., &c., has been appointed Surgeon to the Teignmouth, Dawlish, and Newton Infirmary, vice H. J. Edwards, resigned.

SCOTT, Mr. A., has been appointed House-Physician at Guy's Hospital.

SMITH, W. F. E., M.B., C.M., has been appointed Medical Officer to the Wildon District of the Orsett Union.

STOCK, Mr. W. F., has been appointed Public Analyst for the County of Durham, vice Edger.

STREET, A. F., M.A., M.B., M.R.C.S.E., has been appointed House-Surgeon at the Royal Infirmary, Manchester.

THOMAS, Mr. W. J., has been appointed Public Analyst for the County of Glamorgan.

VACHER, F., F.R.C.S., L.R.C.P., has been appointed Public Analyst for the Borough of Birkenhead.

WATTIE, A., M.A., M.B., C.M., has been appointed Assistant Medical Officer to the Crumpsall Workhouse, Manchester.

WHITE, Mr. W. H., has been appointed House-Surgeon at Guy's Hospital.

WILMOT, T., L.R.C.P.L., M.R.C.S.E., L.S.A.L., has been appointed House-Surgeon to the Bradford Infirmary, vice Roberts, resigned.

METEOROLOGICAL READINGS.

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

We cannot prescribe, or recommend practitioners.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET to be addressed "To the Publisher."

A MEDICAL TRIAL AT THE ANTIPODES.

A CASE has been tried at the Supreme Court, Melbourne, in which one of the surgeons of the hospital of the town, Dr. Stirling, had to answer the charge of unskilful treatment of a stung middle finger of a patient. The damages were laid at £500. It appeared that Dr. Stirling incised the injured finger, and after several weeks the cuts healed, leaving the hand partly disabled. All the professional testimony seems to have been favourable to the propriety of the treatment adopted. The injury was inflicted nine days before application was made for surgical relief, and the finger presented on examination a swollen and inflamed appearance, deep fluctuation existing along the member back and front as far as the palm. The patient had been sleepless for several nights, and there was serious constitutional disturbance. The Judge summed up strongly in favour of the defendant, and (says the *Australian Medical Journal*) "the jury returned a five-sixths verdict for him. As usual in such cases, the plaintiff is unable to pay the costs of trial, and therefore, though Dr. Stirling won his cause, he will be put to considerable expense." The unanimity of the professional witnesses in this case is gratifying, and we hope is not singular at the Antipodes.

Vertebrata should apply to the Secretary of the College.

ADVICE AND MEDICINE FOR SIXPENCE.

To the Editor of THE LANCET.

SIR,—The strictures of the *Chemists' Journal*, quoted in your issue of July 24th, may in some few cases be deserved; but I am sure the stock-in-trade of a dispensary doctor differs very little, if at all, from that of the more orthodox practitioner. Some man, I am sorry to say, think more of saving their own pockets than of restoring their patients' health; but their judgment is swift, as people, finding little benefit from their medicine, go elsewhere. On the other hand, a man giving good drugs and good advice will make a fair profit even if he charges sixpence only for medicine and advice. His expenses being small, he can, and ought to, afford his patients good drugs. Opening my day-book at random, I find the following contained in the mixtures given:—Dec. aloes co., tinct. nuc. vomica, tinct. capsic., liq. morp., pot. bromid., pulv. rhei, tinct. ferri, tinct. bellad., æther sulph., ol. cajuput, &c. I might add several more; but I hope these will show you that all dispensary doctors are not deserving of being classed with "quacks," for I cannot think that I am alone in trying to do my utmost for my patients.

Yours truly,

L.S.A., L.F.P.S.G., &c.

London, July 27th, 1880.

PERUVIAN BARK.

MR. CLEMENT R. MARKHAM is, we hear, about to publish "A Popular Account of the Introduction of Peruvian Bark into British India and Ceylon," accompanied with information of the extent and progress of the cultivation of the drug. We need scarcely say that the name of the author affords a guarantee of the value of the forthcoming work.

Partner.—A little more should be charged for club and union practice; but how much must depend on local circumstances, best known to the parties immediately concerned.

A. C., (Queen's-grove.)—Apply to Messrs. Corbyn, Pharmaceutical Chemists, Holborn.

Births, Marriages, and Deaths.

BIRTHS.

BOLTON.—On the 20th ult., at Kustendjie, Roumania, the wife of A. Irwin Bolton, M.B., A.B. T.C.D., Medical Officer to the Danube and Black Sea Railway Company, of a son—Aby Bourne Corner.

BRUCE.—On the 2nd inst., at Norland-square, Holland-park, W., the wife of Peter Bruce, M.R.C.S.E., of Valparaiso, of a daughter.

DAY.—On the 3rd inst., at Clayton House, Chapel-street, Pentonville, N., the wife of W. Henry Day, L.R.C.P., of a daughter.

FAUSSET.—On the 6th inst., at Tamworth, the wife of Herbert J. Fausset, M.D., of a daughter.

HARRIS.—On the 6th inst., at Upper Berkeley-street, Portman-square, W., the wife of Dr. Vincent Harris, of a son.

PIGGOT.—On the 4th inst., at Beckenham, Kent, the wife of Allen Piggot, M.R.C.S.E., L.R.C.P., of a son.

THOMPSON.—On the 8th inst., at Cranley-place, South Kensington, the wife of R. E. Thompson, M.D., of a son.

MARRIAGES.

HORSFORD—SPARKHALL.—On the 5th inst., at St. Mary Abbott's, Kensington, Joseph Alphonse Horsford, M.R.C.S.E., of Long Melford, Suffolk, to Ada Mary Sparkhall, of Ashbourne House, Holland-road, daughter of the late John Sparkhall, Esq.

LEECH—TOMMAS.—On the 10th inst., at St. Cuthbert's, Birmingham-heath, by the Rev. W. H. Yarleton, M.A., Vicar, Henry Richard Leech, L.R.C.P., L.R.C.S., only son of Henry Leech, of Nantwich, to Catharine Elizabeth (Katie), eldest daughter of Robert Tommas, of Winsor-green.

RICE—HARDWICKE.—On the 11th inst., at St. Stephen's, Tonbridge, George Rice, M.R.C.S.E., L.R.C.P., of Derby, to Constance, youngest daughter of Eugene Hardwicke, Esq., of Tonbridge.

SMITH—GRAHAM.—On the 6th inst., at Mossknow, Dumfriesshire, H. Fowle Smith, M.D., D.I.C., of Waterside, to Clementina Mary, youngest daughter of Colonel Graham, of Mossknow.

SPURGIN—PARKINSON.—On the 5th inst., at St. Mary's, Islington, Thomas Spurgin, M.R.C.S.E., L.R.C.P.E., of Moreton Ongar, Essex, to Anne Andrew, eldest daughter of Samuel Parkinson, Esq., of Canonbury, London.

DEATHS.

BIDDEN.—On the 29th ult., at Hull, R. C. Bidden, M.R.C.S.E., aged 71.

BOSWELL.—On the 20th ult., at Upper Norwood, William Boswell, Esq., M.D., F.R.C.S.I., of Quebec.

BEVAN.—On the 1st inst., at Rickingham, Suffolk, T. K. Bevan, M.D., son of the late Venerable Archdeacon Bevan, Vicar of Carmarthen.

DRYSDALE.—On the 7th inst., at Hillend, Linnithgowshire, John Drysdale, M.B., L.R.C.S.E., F.R.P.S.E., late of Uphall.

WILLIAMS.—On the 6th inst., at his residence, Hayes Lodge, Cheltenham, William White Williams, M.D., F.R.C.P., late Medical Superintendent of the County Lunatic Asylum for Gloucestershire. Friends will please accept this intimation.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

JUSTICE TO ONE'S LOCUM TENENS.

A CORRESPONDENT, opportunely, and in a good but somewhat too long letter, claims a little more justice, if not generosity, for *locos tenentes*. He complains that practitioners nearly always underrate the amount of work to be done by a locum tenens. His instances are striking: "Not a confinement in the month may mean six, eight, or ten; four or six people a day to see may mean an average of thirty." Our correspondent once had a principal who "hoped he would go out often to croquet and lawn tennis, to tea, and for the evening," when often he did not return from his second round till 8 P.M., there being then many callers." It is certainly but fair that on the master's side there should be great candour. As it is the season when practitioners sigh for faithful representatives in their absence, and when they are often disappointed, we admit the plea of one who for many years has acted in that capacity. A little more justice and generosity on the part of principals would perhaps produce a little more faithfulness on the part of assistants and *locos tenentes*.

TREATMENT OF SCARLET FEVER BY WARM BATHS.

To the Editor of THE LANCET.

SIR,—In December, 1869, whilst we were experiencing a very severe epidemic of scarlet fever, there appeared in THE LANCET a reprint of a letter by Dr. Charles T. Thompson, strongly advocating the use of warm baths in this disease, and stating that he had pursued the practice for fifteen years, and had never lost a patient.

In consequence of this communication, I commenced this practice ten years ago, and have followed it from that time to the present. At first I order the patient to have three warm baths daily, to be kept in from three to five minutes, rapidly dried, wrapped in a blanket, and returned to bed. As the disease subsides, I reduce the baths to two or one daily. I find that—1st, it brings out the rash; 2nd, reduces the temperature; 3rd, soothes the patient; and when this treatment has been adopted at the onset, I have as yet not lost a single patient.

In one case the warm bath was objected to till the child had been ill some days, and this case, and this alone, proved fatal.

My friend Dr. Alfred Hollis, of Freshwater, has told me of the great comfort he himself experienced from warm bathing when suffering from the disease; and, of course, in the treatment neither medicine proper nor good nursing is precluded.

Some of my readers may recollect a case of small-pox published by the late Dr. Stokes, of Dublin, where the warm bath proved singularly beneficial, and who doubted not that the mortality in small-pox hospitals would be greatly diminished by the use of the bath. The case I refer to was that of a medical student, in which "the pustulation was almost universally confluent; the purulent matter highly putrescent; the hæmorrhagic state developed; the body one universal ulcerous sore, and the blackness of the worst purpura developed; the odour of an intensely pungent and offensive character, which seemed to pass through the bystander like a sword. Stimulants alone, freely and constantly employed, seemed to preserve the patient alive. The pulse was rapid, weak, and intermittent, and for several days life was despaired of. At this juncture Dr. Stokes happened to describe the case to his colleague, Mr. Smyly, who suggested the trial of the warm bath. Pillows were adjusted in one, the patient placed in it, and the effect was instantaneous and marvellous. The delirium immediately ceased. The patient exclaimed, 'I am in heaven! I am in heaven! Why didn't you do this before?' He was kept at least seven hours in the bath, brandy being freely administered, and removed to bed. The bath was repeated next day, after which he fell for the first time into a tranquil slumber. From this time recovery was progressive."

This may seem a digression; but the treatment of another of the exanthemata by similar means is not inapposite.

My ten years added to Dr. Thompson's fifteen make twenty-five years' experience of a treatment which I can confidently and heartily recommend.

Yours truly,

W. VAUDREY LUSH, M.D., &c.,

Weymouth, July, 1880. Physician to the Dorset County Hospital.

HOMBURG.

To the Editor of THE LANCET.

SIR,—The season at Homburg has commenced auspiciously, so far as the German and French visitors are concerned, and the Elizabeth Brunnen has many visitors in the early morning to receive its refreshing water. There is, however, a lack of well-known English faces, and many attribute this to the rumours of disease being in the town. Such rumours are false. Homburg was never healthier, as official records and medical testimony show. More, the sanitary arrangements of the best hotels are equal to those at home, and superior to any other Continental watering-place I have seen. Cases of sporadic disease occur everywhere, but that fever, diphtheria, or any other zymotic disease exists is untrue, and it is a pity that unfounded suspicion should prevent those who would otherwise do so paying their annual pilgrimage to the most charming of all "health retreats."

As this is my fourth season at Homburg, I may be presumed to know the town well, and I consider it right to tell, through your columns, my professional *confrères*, not to be frightened to advise those requiring it to come here as of old.—Your obedient servant,

Homburg, Aug. 4th, 1880.

MATTHEW CHARTERIS, M.D.

THE INDIAN MEDICAL DEPARTMENT.

To the Editor of THE LANCET.

SIR,—The recent changes in the Indian Medical Department have caused much anxiety to all its members, and if the Government of India wish the service not to become unpopular they will have to take some steps to remove the present state of discontent. I will confine my remarks to the subject as it affects the officers who have entered the service since 1864. The more senior officers have different grounds of complaint.

1. Under the new rules, all chance of rising to be the head of the service in the military branch has been taken away.

2. The chances of rising to the administrative appointments of either a deputy surgeon-general or surgeon-general have been greatly diminished, there being now only eighteen of these appointments instead of twenty-six. The grant of this rank to five sanitary commissioners, under certain rules, does not make up to the service for the loss of the eight appointments.

3. Junior officers are kept too long on the unemployed rate of pay of their rank after passing the vernacular test. If they are posted to "officiating appointments," they draw a little more, but they do not, as a rule, for many years draw pay equal to the scale laid down in the Memorandum supplied to each candidate at the India Office.

4. Junior officers who have no regular appointments are often detailed to work in appointments for which there are no allowances fixed by regulation, and consequently are kept on the unemployed pay of their rank.

5. Officers of the Indian Medical Department only rank as lieutenants for the first six years of their service, and draw a lower rate of pay than the officers of the Army Medical Department while at Netley.

6. There is no grade of brigade surgeon in the Indian Medical Department.

7. There are not sufficient officers in the Indian Medical Department for the work, and even the authorised establishments are not kept up to their full strength as they ought to be.

8. The regulations regarding leave and furlough, as laid down in the Memorandum, are not acted up to, and it will never be possible to carry them out unless more officers are employed. Furlough, except on medical certificate, has only existed in name for many years, and privilege leave can scarcely ever be obtained.

9. One effect of the department being kept so short-handed is that junior medical officers are moved about from station to station far more than is either good for them or the service.

10. In the Memorandum before referred to, the minimum rate of pay laid down for an officer to draw on furlough is £250 per annum. This is not carried out, as junior officers going home on sick leave draw less than that amount.

11. The rates of pensions contrast unfavourably with those of the Army Medical Department, and are so low that officers, unless they have saved a good deal of money, will find it impossible to retire on them. Government ought to grant the Indian Medical Department at least the same rates of pension as those of the Army Medical Department.

12. The appointments to be held by the commissioned officers of each branch of the service (Bengal, Madras, and Bombay) ought to be clearly defined, and the Government of India should insist on their being filled up, in accordance with this rule, by officers of the branch to which they belong, unless under any extraordinary circumstances.

13. The rule that has been laid down by the Government of India regarding the employment of others than commissioned officers in appointments sanctioned for commissioned officers ought to be insisted on.

14. The step of honorary rank on retirement should be given after twenty instead of twenty-five years' service.

15. The question of honours and decorations is a delicate one; but surely more officers of the Indian Medical Department than those who have been decorated have earned them.

16. If these difficulties were removed, the Indian Medical Department would still remain the most popular of the medical services. None of the others can offer the same prize to young medical men. The Indian Government in most cases acts fully up to its promises. When it does not appear to do so, as in some instances I have pointed out, it is, I believe, because the subject has not been properly brought forward by the departmental authorities. There is no medical service in which a man is so well treated if his health breaks down, or he becomes unfit for further service in India.

17. I have not attempted to touch the subject of organisation; but it seems to me curious that the Government of India offer the same pay &c. to natives of this country and to country born men as they do to Europeans, when they could get the same class to serve them for much less.

18. If they did decide to have Europeans only in the commissioned ranks, would it not be far better and more economical for them to fill up all the Indian appointments, both military and civil, by volunteers from the Army Medical Department? In such a case the medical department in India should be under the Indian Government, as the officers of the Royal Engineers serving in India are at present.

I am, Sir, your obedient servant,

Madras Presidency, June 16th, 1880.

AN OLD SUBSCRIBER.

THE POTATO.

WE have already (THE LANCET, July 24th) had occasion to refer to the conclusions of the Select Committee appointed to inquire into the best means of diminishing the frequency and the extent of failures in the potato-crop. The report of the Committee, with the evidence given before it, has now been published, and forms a Blue-book of exceptional, we might say of painful, interest having regard to the part which repeated failures of the potato-crop have played in the health-history of the sister kingdom, and the part which the last failure is now playing. The scientific evidence tendered to the Committee puts the reader in possession of the existing state of our knowledge regarding the disease, which proves at times so fatal to the plant, and the agricultural evidence tends to show in what direction effort must be made if we would hope to diminish the ravages of the disease in the future. This would appear to be by the continuous search for and cultivation of new healthy stocks; and the Agricultural Societies of the United Kingdom and Ireland failing to undertake this task, the Committee are of opinion that it should be entered upon by the Government.

THE BLOOD IN ANÆMIA.

To the Editor of THE LANCET.

SIR,—In your columns of July 17th, in a communication from Dr. Hunt on the Blood in Anæmia, the following passage occurs: "Not unfrequently have I examined the blood of young girls attending my out-patient room, expecting to find a marked diminution in the number of the corpuscles, and to my surprise found it normal or nearly so." The following read in connexion with the foregoing passage is, I think, of interest:—

Last spring I had under my care a patient in whom by exclusion the diagnosis of a cancerous enlargement of the liver had been arrived at. Many of the positive signs of cancer were absent or difficult to perceive. The patient, who was suffering from intense anæmia, anorexia, and feebleness, asked me to accompany him to Europe. In Marseilles, after several consultations with M. le Dr. Combalat, Chirurgien-en-Chef des Hôpitaux, who was loth to admit the diagnosis of cancer, M. le Dr. Girard, Médecin-en-Chef, was asked to meet us both in consultation. After a careful examination and review of the history of the case, they jointly expressed the opinion that the case was one of pernicious anæmia, and that the enlargement of the liver was consequent on this. If, however, this was not the disease, the case must be one of cancer. A numbering of the blood-corpuscles was made by my friend Dr. Charles Livon, acting Professor of Pathology in the School of Medicine at Marseilles, with the result that, out of a mean of five observations, the cubic millimetre contained 5,765,156 red blood-corpuscles.* The hæmacytometer used was that of Nachet. Both of us were astonished at this result in a patient who presented all the signs of anæmia in the most marked degree, judging by the colour of the mucous membranes and nails.

At the next consultation, Drs. Combalat and Girard were equally struck by the result, to such an extent that they wished to have a second numbering made by another observer. Unfortunately I was unable to find anyone else in the town who could undertake this. I may add, however, that I myself was present at the numbering, and made one observation myself, which was quite in accordance with the mean of Dr. Livon's observations, which were made on two successive days at four in the afternoon and eleven in the morning respectively.

Ten days later the patient died, and at the autopsy mesenteric cancer was found, with deposits in the liver.

It appears, then, that pallor of the mucous membranes and nails may be caused by three things: (1) A diminution in the number of red blood-corpuscles; (2) a diminution in the quantity of hæmoglobin; (3) an increase in the number of white blood-corpuscles, as in leucocythæmia. To these, I think, a fourth might be added—viz., a diminution of the normal volume of blood for the weight of the body; the diagnosis of this could be established by the exclusion of the other three. The expression "anæmic condition" ought not to be understood to convey anything more than pallor of the mucous membranes &c., and, according to the observations of Dr. Gowers, Dr. Hunt, and those here narrated, cannot express *per se* a deficiency of blood-corpuscles.

I am, Sir, your obedient servant,

Cairo, Egypt, July 24th, 1880. T. E. MACLEAN, M.B. Lond.

G. P. R.—The meeting of the American Association for the Advancement of Science will take place at Boston on the 25th of August.

Constant Subscriber.—We cannot depart from our rule.

A HINT.

To the Editor of THE LANCET.

SIR,—Phthisical subjects often experience great benefit from a long sea voyage. Fresh sea-air is probably the main medicine; but at a time when antiseptic inhalations are being favourably employed in the treatment of phthisis, it may be well to inquire whether the presence of large quantities of tar may not exercise a favouring influence. That the air of a ship is thoroughly and permanently impregnated with this antiseptic material, our noses can testify.

I am, Sir, yours truly,

Clifton, Bristol, Aug. 7th, 1880. GEORGE BUDD, Junior.

* The mean number of white blood-corpuscles in the cubic millimetre was 7382.

GUY'S HOSPITAL.

To the Editor of THE LANCET.

SIR,—Whilst heartily sympathising with the tenour of your leader of August 7th, called forth by the recent lamentable occurrence at Guy's Hospital, may I be permitted to utter one word of protest. It appears that while nursing sisterhoods have come under your just censure, the very principle of ladies acting as hospital nurses has been included in the general condemnation. You desiderate for the patients of our hospitals "a fair number of women of their own class, trained to do their business as nurses at the bidding of the medical officers," and elsewhere you allude to "a corps of women who, in all the energy of their discontent at the natural subordination of their sex, have seized on nursing as a sphere for the vent of their emotional natures." I am unable to acknowledge the justice of these observations. Let the authority of THE LANCET be directed against the ecclesiastical element, which has with malign influence mixed itself with hospital nursing, and which finds expression in the terms "sister," "sisterhood," but do not let it be used to discourage ladies from entering on a life-work essentially feminine, and in which education and refinement so materially and beneficially contribute to efficiency as in nursing. The evils complained of do not originate in the fact of the nurses being ladies, but in the fact of their being united into sisterhoods, and invested with a kind of corporate authority—an authority which, when combined with ecclesiasticism, gives rise to the most noxious developments.

My personal knowledge does not extend to other Scotch schools; but, as regards Edinburgh, I can state, from ample experience as a student and house-surgeon, that the lady nurses in the infirmary there are the greatest possible blessing, alike to patients, students, and teachers. They combine intelligence, refinement, and kindness in a manner almost unknown among the nurses of an earlier date. They exercise a distinctly good influence in the wards, and their general efficiency and skill is in the highest degree satisfactory. This testimony will be corroborated, I believe, by everyone acquainted with the Edinburgh hospital. But the Edinburgh nurses are not sisters. They have neither power nor inclination to control either the medical treatment of the patients or the arrangements of the hospital. They belong to no organisation, and are subject alone to the authority of the medical officers. In a word, they are simple hospital nurses, with the difference that they are ladies. Were the metropolitan hospitals as happily situated, we should hear less of the encroachments of "sisters," and THE LANCET would not find it necessary to discountenance ladies in the adoption of a profession for which they are so eminently suited.

I remain, Sir, yours &c.,

Weston-super-Mare, Aug. 8th, 1880. ROBERT ROXBURGH, M.B.

To the Editor of THE LANCET.

SIR,—In a report of the Committee of the Governors of Guy's Hospital appointed to inquire into the nursing difficulty, it is recommended that once a month, or oftener if necessary, two members of the medical staff be invited to attend the Committee, with the view of deliberating on any matters relating to the medical and nursing arrangement; that in any difference of opinion, the views of the medical staff, as well as those of the Governors, be recorded in the minutes. The Committee believe that the above arrangement would be a help to the Treasurer and Governors, "and at the same time it would afford the medical staff an opportunity (the want of which they have felt) of personally coming in contact with the Governors." In how many of our hospitals have the medical staff been entirely ignored in the management of those institutions completely dependent on medical services for their success and utility?

Yours &c.,

F.R.C.P.

August 10th, 1880.

To the Editor of THE LANCET.

SIR,—Referring to the recent unfortunate occurrence at Guy's Hospital, would it not be useful to elicit the opinions of medical officers of other hospitals whether it is desirable to put the name of the disease on the bed-head ticket of the patient? Yours faithfully,

August 10th, 1880.

HOSPITAL PHYSICIAN.

To the Editor of THE LANCET.

SIR,—I observe that Mr. Francis Wilson, in his evidence at the trial, stated that the prisoner, Louisa Ingle, was "the daughter of a surgeon in good practice." This is not correct, at least as respects this country, my brother and I having been the only persons of that name on the Medical Register for nearly twenty years, and she is no relative of ours. Yours truly,

Cambridge, August, 1880.

ROBERT N. INGLE, M.D.

DRUNKENNESS OR APOPLEXY?

To the Editor of THE LANCET.

SIR,—On August 5th, at 8.30 P.M., I saw a woman at her own house. She was lying on the floor of her room, occasionally breathing stertorously; both pupils widely dilated, the right most so, the left contracting feebly; when the candle was brought close, the right totally insensible to light. She was quite unconscious. Her husband said she had been drinking brandy freely for a week. I had attended her frequently for the effects of her drinking bouts, but had never seen her unconscious before. About twelve o'clock she came round, and in twenty-four hours she was all right. I confess I was in a difficulty about the diagnosis.

Yours obediently,

Wansford, Aug. 7th, 1880. FERGUS M. BROWN, L.R.C.P. Ed.

Address in Physiology,

*Delivered at the Meeting of the British Medical Association
on Aug. 13th, 1880,*

By MICHAEL FOSTER, M.D., F.R.S.,

PRÆLECTOR OF PHYSIOLOGY IN TRINITY COLLEGE, CAMBRIDGE.

MR. PRESIDENT AND GENTLEMEN,—When I took the invitation to deliver the Address in Physiology out of the hands of your Council, it was in my mouth sweet as honey, as, I suppose, my predecessors in this honourable position know; but bitterness came when I began to consider what I should say. While pondering over the choice of the words which I might address to you, I began to be haunted with a fundamental question. On the background of my dim and obscure thoughts, there stood out, with vivid and importunate distinctness, the sentence, *What is this Physiology* which is to form the subject of the address? And I felt that no words would be given to me until I had framed some satisfactory answer to this initial question.

Looking around for a firm basis to start from, we find it admitted on all hands that physiology is a branch of the science of living beings. Looking more closely into the matter, we find that all living beings are capable of being studied under two aspects. In the first place, they possess characteristics of form—external and internal, superficial and deep—which distinguish them from things which are not living. In the second place, they act upon, and are acted upon, by the world around them in ways which are not possible to lifeless things. The former considerations supply the basis of the science of morphology; the latter, that of physiology proper. All living things may be studied independently from either of these points of view. Were it possible to arrest for a while, without collapse, the multitudinous movements of the universe, were the whole sum of things to fall into a sleep deeper than that fancied by the laureate in his poem of the “Day Dream”—a sleep deeper than this, namely, one which also stayed all growth and stilled the molecular whirlpools of the tissues,—were all things to be fixed in immovable rigidity, as by a sudden petrification, there would still be ample material for collecting data and elaborating laws of form, distinguishing the things which we now call living; there would still be scope for the morphologist, though, in the absence of all action, the physiologist would be without employ. Conversely, we can readily imagine a state of things in which the pulses of the movements of a living being might be investigated, the products of chemical activity determined and measured, its actions and reactions studied, though itself was never seen, and its outline and structure remained unknown. Such a condition would exemplify a physiology existing without any corresponding morphology.

Here, probably, some one will object that form is an essential factor in many physiological problems; that, for instance, in the movement of a limb, the character of the result is determined by the relative positions of the bones, tendons, and muscles. That is undoubtedly true; and the same objection may be urged in reference to many other physiological problems. But it is also true that the distinguishing token of the movement of the limb of a living being—that which differentiates it from the movement of the limb of a dead machine—is the fact that the movement is brought about by *muscular contraction*; that mysterious molecular changes in a peculiar tissue, and not the burning of fuel in a furnace, or the falling of water from a height, or the blasts of the wind, supply the energy of the movement. The true physiological problem involved in the swinging of an arm is how it is that certain muscles suddenly grow short, and not the problem how that shortening manages to produce the particular movement in question; the latter problem might occur in any dead machine, and is a purely mechanical problem; the former is the only one distinctive of the living being, and, for its solution, study of form, so far, has given us no help.

The two branches—morphology and physiology—run their several courses along lines which at present seem parallel; No. 2973.

I say, at present, because we can even already see that in the future they will converge and meet. The science of morphology will receive the crowning of its edifice when the forms of living beings can be fully explained by the action of the environment on the living substance; and the science of physiology will similarly be perfected when the actions and reactions of a living organism can be predicted from the molecular structure of its constituent tissues, just as now the superficial character of some of its motions can be explained by the mere mechanical relations of its constituent parts. But that time is still far distant, and we may at present rest content with the view that physiology is the study of the actions and reactions of living beings; and the instance I gave just now of the movement of a limb may be taken as a type of all physiological problems. Whatever action of living organism we examine, whether of a vegetable or of an animal, be it a matter of the circulation, or of digestion, or of the nervous system, or what not, we find that the problem suggested by that action is incrustated, it may be, with a shell (sometimes thick and hard to crack, sometimes thin and easily brushed away) of questions of a purely mechanical or physical or chemical nature—questions which might present themselves in reference to any action of either living or not living matter; but that within the shell there is the kernel question; and that, whether it be the construction of a muscle, or the molecular changes of a secreting cell, or the molecular agitations of an excited nerve, is the true physiological question—the question which cannot be studied elsewhere than in a living frame, the question towards the solution of which knowledge of form and shape (short of molecular construction) gives little or no help; the question of all importance, the answer to which comes reluctantly and slow. But it has long ceased to be the guiding idea of physiologists. It received its death-blow when Claude Bernard made known the fact that in the liver, that organ of which we were previously content to say that its function was to secrete bile, a mysterious formation of glycogen took place; and all modern inquiry sets its face more and more away from such a view.

The animal body may, indeed, as a whole, be likened to a machine, inasmuch as it is full of intricate and delicate harmonies of checks and counterchecks, whereby the turmoils of its molecular agitations, the swift whirling of its inner wheels, are cunningly adapted to work out the smooth result which we call healthy life. The animal body, moreover, is full of deftly built machines; it is studded with bits of apparatus—mechanical, hydraulic, optic, acoustic, and the like. But the physiologist who is pressing forward to the solution of the wider problems opening up at the present time before him no longer enters on his work in the spirit of one who, placed in the midst of a collection of ingenious inventions, sets himself to discover the purpose and working of each; on the contrary, he becomes day by day more convinced that the key which will unlock the mysteries of life is an understanding of the broader laws of that conflict of atoms which is going on in every tissue; that perpetual building up and breaking down; that molecular strife which appears now as the piling up of material in growth, now as the rush of a secretion, or the shock of a muscular spasm, or the thrill of a nervous impulse. Whatever part of physiology he may take up, sooner or later he finds himself face to face with problems of this kind, compelled to desert the question of special function, driven to search into the more general characters of living matter. The physiology of function and organ forms but the outer court of the science itself. The discovery that the secretion of gastric juice is the function of the stomach, of the gastric glands, of the central cells of those glands, is hardly more than the prelude to the inquiry into the nature of those changes in the protoplasmic network of the cell, whereby, amid the coming and going of granules, the shrinking and swelling of the cell, the crumpling and unfolding of the nucleus, water containing salts and the mysterious pepsin trickles into the lumen of the gland; and that search leads the inquirer away from the gastric cell to the parotid or the lachrymal, and from that to the hepatic cell, and thence to the renal, and before long possibly he will be seeking an answer to his question of the gastric gland by knocking at the door of the muscular fibre or the retinal epithelium. The discovery that the function of the gastric juice is to digest proteids is but the first step of the inquiry, What is the nature of proteolytic digestion? and that leads away to a far-reaching search into the structure of the proteid molecule and its relation to cyanic radicals. The discovery that the function of the cerebellum is to co-ordinate

movements thrusts us at once into a quest after clearer notions of the nature of co-ordination, and that beckons us on to studies of the molecular oscillations which we call sensory and motor, and these bring us back again to the muscular fibre, and then to the simpler protoplasm of the undifferentiated cell.

I might multiply to weariness illustrations such as these of the tendencies of modern physiology. I will, however, content myself with pointing out that these extensions beyond simple organ and function are not mere idle speculations. It little boots either the sick man or the sound man to know that the function of the stomach is to secrete pepsin, or of gastric juice to digest proteids, unless he be master of the conditions affecting the character of the secretion or the potency of the juice. And these extensions I am speaking of are simply efforts to understand these very conditions, to explore the laws by virtue of which the amount and character of each drop of juice which falls into the cardiac pouch is determined by the vibrations of a cerebral cell, or the labours of the hepatic tissue or the temperature of the cutaneous nerves.

But if this conception of physiology be admitted a most important deduction follows—no less a one than this, that all distinctions between pathology and physiology are fictitious and unreal. Indeed, if we even simply look at the matter from an *à priori* point of view, we must arrive at a somewhat similar conclusion. For what should we say of the kindred science of meteorology if it were divided into a normal science of bad weather, and an abnormal separate science of fine weather? Undoubtedly there are bad days and good days; there are happy conditions which we may call health, and there are unhappy conditions which we may call maladies, and the one may present superficial problems which are absent from the other; but directly we leave the outside of each, directly we attempt to grapple with the fundamental questions lying at the bottom of each set of conditions, we find we are in each case struggling with the same things. Thus, as an example, if there be one word which is more clearly the “note” of pathology than any other it is the word “inflammation.” So long as the questions about inflammation were of the outside, of the shell only, so long a cabalistic doggerel *tumor, turgor, rubor, et dolor*, formed the centre for the pathologists’ discussions, so long as the physiologist was content to tarry in the mere mechanical problems of the circulation, each might fitly go on his own way heedless of the other’s doings. But directly the pathologist puts to himself the question, What are the processes which lie at the bottom of, which are the causes of, this *tumor* and *turgor*? directly the physiologist began to ask himself, What are the fundamental laws governing the capillary circulation—each found himself working at the other’s problem. It was as a physiologist, working by methods only physiological, that more than a quarter of a century ago, one who has since achieved the highest renown as a practical surgeon, but whose career physiologists selfishly deplore as having withdrawn from their midst a puissant captain—I mean Joseph Lister—carried out those remarkable researches which opened up an epoch, on the one hand, as regards inflammation, on the other as regards the circulation. It has been through methods purely physiological at the hands of Cohnheim, and others, that our knowledge of inflammation has since been advanced. On the other hand, the physiologist who is inquiring into the abstruse problems of the capillary circulation, finds that the only path to progress lies through the study of changes of a more or less inflammatory nature, naturally occurring or purposely induced. And what I have said of inflammation may also be said of other so-called morbid processes; indeed, of all the phenomena, both structural and dynamical, of disease. The famous cellular pathology is in reality a physiological essay; and for these many years past the progress of pathology has been marked by investigations, pathological it may be in name, but physiological in scope and method.

The view, then, which I would venture to urge respectfully on your serious attention to-day is, that physiology is not a collection of curious problems concerning the living organism in an abstract ideal condition called health; it is not simply the answer to a series of questions, what is the normal function of this and that organ? Fundamental as distinguished from superficial physiology, it has before it the task of investigating the elementary properties, we might say the molecular movements,

of living matter (including matter which is becoming alive, and that which is ceasing to live), those movements, the varied combinations of which come to light in the effects which we may, if we like, call functions. In this investigation it recognises none other than the superficial distinction between the normal and the abnormal, the healthy and the diseased; it joins hands with pathology for its aims, its subject matter, its methods are the same. Both are sciences partly of observation, partly of experiment; that is to say, while both find a certain amount of material on which to work in phenomena which present themselves without interference on their part, whether it be the phenomena which, running easily in the grooves of the universal machine, we call normal, or in the irruptive, troublous, often times horrible phenomena of disease, which an older writer, in prophetic irony of the humanitarian schools of to-day, once called nature’s experiments—while both, I say, find often times food enough for reflection in the events which nature herself brings before them, both find themselves helpless to gain the solution of their problems, unless they themselves intervene and directly bring about the state of things which they desire to study. The physiologist in his daily walk, or the pathologist in the hospital ward, observes an incident, and at once sees that a variation in that incident will afford a complete or partial solution of the phenomena. If he goes into the laboratory, he may artificially produce that variation while the problem is still fresh, still troubling his mind. Otherwise he must wait, carefully storing up in his mind the memory of the incident and its suggestions, till in some other walk or ward he meets with the desired variation; he may not meet it till old age has dimmed his memory and enfeebled his mind, or he may never meet it at all. It may be granted that generations of alert, active-minded men, ever observing, ever recording, ever reading and making use of the records recorded, might in the long course of ages have an opportunity of observing, as natural occurrences all the phenomena of living beings, including everything that may be brought to light by laboratory experiment, for nature is a relentless, untrammelled vivisector, and there is no secret of the living frame which she has not and will not, at divers times, lay bare in misery and pain. This may or might be granted, but life is short, and how long would the search be which thus waited at every step for nature’s signal? Life is short and also painful, and even on mere so-called humanitarian grounds we may refuse to sit still as fatalists, and let the pain and wrong of life accumulate till nature in some wayward mood does for us the experiment which we might ourselves do to-day.

A physiology and pathology founded on observation alone may not be impossibilities; but that progress of science which is demanded by human needs, and which at even its best is slow, is impossible without experiment.

If what I have urged be admitted, then it is obvious that the pathologist—and I need hardly say that by the pathologist I mean the inquirer, the investigator—will do well to get himself early trained in physiological studies. He will thereby not only learn under simpler conditions the methods and the means of which he will hereafter make use, but he will be practised in the solution of problems identical in absolute nature with, but of an easier type than those to which he may afterwards direct his labours. Conversely the physiologist, though his own narrower field affords material ample enough for his best energies without his ever leaving it, is unworthy of the name if he affects to despise or neglect evidence because it is of pathological origin.

I may, perhaps, to some of my hearers appear to be threshing well-trodden corn. They are willing at once to admit as a commonplace truism all that I have urged. But, if what I have said be so commonplace in words, how is it when I look around it does not appear to me to be so commonplace in deed? I speak under correction, but surveying our numerous medical schools, reading our medical literature, and watching the results of medical inquiry in this country, I cannot avoid the conclusion that pathology, as commonly understood amongst us, too often either means a barren discussion of the doctrines of the schools, verbal disputes better fitted for the dialectic energy of the leisurely school-men of old than for the practical needs of our busy age, or is regarded as identical with a pathological anatomy, in which a luxuriant, I might, perhaps, say a rank growth of facts and minutiae, cultivated for the sake of their clinical importance, has choked the tender plant of rational, i.e., physiological—interpretation.

If what I am urging is a truism, if it be acknowledged on

all hands that pathology is an experimental science, which, though entering on its inquiries from a somewhat different standpoint, and seeking the solution of questions arising on the somewhat different combinations, deals with the same fundamental phenomena as physiology, uses the same methods, works in the same spirit, and in the end resolves the same problems, where, I would venture to ask, are the pathological laboratories fitted with due appliances, where researches in this science are being carried on? Is it not the case that England possesses at this moment just one institute devoted to pathological inquiry, and that placed under such unfortunate conditions that lately the choice of a director had to be decided on other than scientific grounds. Thanks to the foresight and the insight of John Simon, the sinews of war have not been wanting to young inquirers; but surely if the profession does recognise the need of the real study of pathology, every school of medicine should take its share of labour, and not leave almost the whole task of it at the uncertain bidding of a Whig or a Tory Government, whose ways, however admirable in other respects, are not altogether the ways of science.

If physiology be such as I have so feebly attempted to portray, I trust I shall not be considered as abusing the honourable position in which you have placed me to-day, if I venture now to offer a few remarks on the relation of this physiology to the medical profession at large. Nay, rather I feel encouraged to do so by the reflection that it is the consciousness of the prime importance of physiology to medicine which has led our authorities to place the address in physiology on a level with those of the master arts of medicine and surgery.

Of the relations borne to physiology by those members of our profession who are actively engaged in the investigation of disease, to the professional pathologists, so-called, whether they happily can give their whole time to laborious investigation, or snatch moments for inquiry from the midst of practical duties, I need say nothing. It will be clear that I recognise them as brother physiologists in deed if not in name.

Nor need I tarry to speak of those who, having achieved high success, and, resident in this or that metropolis, live among the latest results of science, and can keep themselves abreast with the progress of physiology by spending an occasional hour at a society, or utilising the opportunities of their dinners and their clubs; nor of those younger men who, placed in much the same position as that of their chiefs save that their success is still in the future, hold free converse with the younger workers in science. I desire, rather, to say a few words on the relation of physiology to the great backbone of our profession (for ours is a vertebrate body), the general practitioners scattered all over the United Kingdom, those who, above all others, bear the heat and burden of the medical day.

Such men have little time for prolonged inquiry. They are not pathologists in the sense in which I have used that word to-day. Far be it from me to depreciate in any way the intellectual value of the healer's calling. Happily, the phenomena of disease are so many and diverse, that it is impossible for the art of medicine ever to become a mechanical routine for curing patients by rule of thumb. Happily, even the most obscure practitioner in the most secluded village is driven to reflect, is forced to take his patient's case in hand as a scientific problem to be solved by scientific means. The salt which secures our profession its savour is the fact that every doctor worthy of the name is stimulated by the facts of his daily life to reason on their why and wherefore, to cultivate a real spirit of pathological inquiry. But his inquiries, save in a few rare cases, are inchoate and fragmentary. It is not in his power to carry out the tedious, the time-consuming, the continued investigations by which even nature's meanest secrets have to be wrung from her. His researches and reflections are rather salutary, inasmuch as they maintain the high spirit of his calling, than fruitful, by reason of the abundance and value of their results.

It is in reference to the practitioner, not as a pathological inquirer, but as a busy healer of the sick, that I would venture to put the question, What has he to do with physiology?

Looking at the matter from one point of view, the answer might seem simple and ready enough—"Nothing at all." I can easily imagine a practitioner who learnt his physiology twenty or thirty years ago, listening while some eloquent young physiologist of a few years' standing explained his views concerning this or that abstruse physiological con-

tion, and the reasons of his divergence from his German brethren, and then going away and reporting to his brother practitioners, "It was all Greek to me; you and I have no more to do with such stuff as that than we have with four dimensions in space, or the inflections of the Telugu tongue." And yet, under another aspect, a quite different answer, it seems to me, has to be given. I spoke just now of the practitioner as a virtual, though not a professional, pathologist. His daily practice is at every step determined by pathological doctrines. Whether we admit it or not, we are all of us, as intellectual beings, the puppets of theories and beliefs; all our actions which do not spring from passion or instinct are the outcome of dominant views. Both the ignorant and the learned are thus alike governed. The village nurse opposes, and often circumvents, the doctor, on the strength of theories which a study of her nomenclature reveals to be broken traditions of the advanced pathological teaching of a century ago; the so-called "practical" man is the most abject slave to theory of all, for his theories are unknown tyrants, hidden from himself. The hand of the practitioner, even the most empirical, is, directly or indirectly, guided by pathological views. His results will, in the long run, be successful in proportion as his views are in accord with those of nature; and assuredly the satisfaction in his calling will be the greater in proportion as an increasing mastery over the rational interpretation of morbid phenomena transforms his daily tasks from a dull routine into scientific inquiry and intellectual effort.

But there are doctrines and doctrines. Not every view which is put forward is true, and even those views which hold a central truth often present a thick crust of error. Biology, moreover, like other sciences, is not an edifice built up by adding brick to brick, the older courses remaining as they were laid to form the support of the later ones. It may rather be compared with the growth of an animal through metamorphosis, but a metamorphosis more protean than that of any living thing. The butterfly is often more like the grub than is the finally accepted form of a doctrine to the crude shape in which it was first put forth. It is not easy to grasp the essential feature of a doctrine as it passes through its several phases; and not once or twice, but often, the creature has been confounded with its envelope, and the last integument treasured as the body itself.

Not only are there shortcomings and errors even in the views advanced by men most competent by their training and their talents to make known their results, but theories and doctrines are promulgated by men who have little or no fitness for the task. No one can study our medical literature for any length of time without observing that again and again some hybrid pathological or physiological theory is thrust upon the world; a hybrid gained, it may be, by fertilising with the pollen of false observation or deduction a true physiological doctrine; a hybrid, like other hybrids, of showy character, destined to win for a while public favour, but, like other hybrids, destined after a while to wither away without producing fruit. Knowledge is doubtless increasing; but errors are likewise abundant. How is the practitioner, living often in isolation, obliged to trust in the decisions of his own judgment? How is he to guard against delusive views?

I was urging just now the fundamental identity of pathology and physiology. No serious advance is made in physiology which is not sooner or later translated into the language of pathology. No real independent advance is made in pathology which does not either show itself to be in accordance with the solid nucleus of sound physiological doctrine, or compel the current physiological teaching to widen its doors and admit a new truth. The best test of a new physiological doctrine is that, if true, it will in nearly every case, when properly applied, help to solve some hitherto insoluble pathological problem. The best criterion of a pathological doctrine is that it will stand the ordeal of searching physiological criticism, and show itself in accord with the trustworthy results of independent physiological inquiry. And possibly no function of physiological science is more important than this of serving as a touchstone by which to try the value (whether they be true or false) of the pathological theories which flutter down on the face of our medical literature thick as the falling leaves of an autumn day. But what is this to the active practitioner? Am I urging that those few golden moments of leisure with difficulty wrung from a hard day's work, which are not given up to the study of pathology itself, should be spent in poring over miserable physiological books? Hardly, though I

think I am not overstating the case when I say that many a practitioner, when he has come to maturer years, arguing to himself somewhat in the line which I have taken to-day, strives by private reading to revive that knowledge of physiology which he neglected, or for learning which he had scanty opportunities in his youth; desirous of some firm standpoint to serve as an outlook over the flood of the new pathology, he seeks to be informed concerning the teachings of modern physiology. But is it not also true that, when he takes up current physiological literature, he finds it to a large extent written in what has to him become almost an unknown tongue? Though a good deal may be old and familiar, a good deal more is new and strange. He remembers, perhaps, hearing in his youth some of the things of which the writers make so much; but he also remembers that, hearing them, he judged them to be subtleties or novelties, interesting doubtless to the lecturer, but not likely to be made the subjects of questions in the examination-room; certainly having no relation whatever to the practical career before him, and therefore matters which might fitly be dismissed from his mind. Now he is chagrined to find that the refinements, the ingenious speculations, the heated controversies of the physiology of his youth, at his lecturer's enthusiasm, over which he used to smile with the smile of practical wisdom, have become the corner-stones of important doctrines of to-day, and form the supporting structures of acknowledged—even of fashionable—pathological views. But it is now too late for him to retrace the long and time-consuming steps of physiological study; he must rest content with a narrower sphere, a more restricted horizon.

This desire of the practitioner is, I take it, an approval and practical proof of the soundness of the argument which I am venturing to urge, with deference, on my present audience; and which may be more succinctly formulated in some such way as this. Pathology, that is, the rational, the scientific, interpretation of the phenomena of disease, is not only the necessary basis for the rational art of healing, and, as such, most to be cultivated by those who are seeking the advance of our profession, but is a no less necessary part of the intellectual equipment of every practitioner who is unwilling to remain a mere machine for the application of therapeutic agents in a dull inanimate way. But the salutary use of pathological doctrines implies the possession of a critical power, so that the false may be sifted from the true; and the building of this critical power, without which each new pathological discovery or conception becomes a sharp two-edged instrument, cutting the hands of him who would attempt to use it—becomes a "will of the wisp," leading into bogs of error—is one of the chief functions, and, for the active practitioner, the most important function of physiological study. This, at least, is the conclusion forced upon us, if we admit what I have attempted to urge to-day—that pathology is a special development of physiology. For physiology, when we attempt to distinguish between the two, is the older, more general study. It deals with simpler, less intricate phenomena; its conclusions are wider and broader, less likely to be disturbed by the perturbations of practical demands, or to be confused by a temporary and delusive practical success. The phenomena on which its doctrines are based are always at hand, and may be called up for demonstration at any time and any place. Each new pathological doctrine, in turn, when it becomes stamped as true, is received into the common body of physiological teaching. And we have every reason to think that, as in the past, so in the future, the truths of physiology will serve, on the one hand, as the starting-points of pathological inquiry; and, on the other, as a tribunal before which each new pathological theory must at its birth be tried.

Two conditions, however, must be observed if the study of physiology is to bear this fruit of critical power. First, the study must be carried on in early years, while the medical mind is being formed, and not left to the chance leisure moments of a busy life; secondly, the study must be an adequate one, having for its end this very object—the acquisition of critical power.

Within the last few months there has passed away from our midst a man who, great in many things, was perhaps especially great as a teacher of physiology. I need hardly say I speak of William Sharpey. And if it be asked what it was that made Sharpey's teaching so successful, I think this answer might be made. It was not the eloquence of his words, or the fluency of his speech. It was not the profusion or the beauty of his stained sections and preparations, nor the exactness, success, and multitude of his lectures, experi-

ments, and demonstrations. It was not that he poured out upon his audience all the treasure of physiological knowledge with which his remarkable memory was stored, for he often withheld much that another might have given. Nor was it because he avoided doubt and confusion by teaching only that which had been ratified by nine years' keeping, for he often expounded to his class the very newest discoveries, and worked his way through many a tangled discussion. It was rather, as I have ventured to say elsewhere, that his method was to lay before his hearers, in plain straightforward language, just how the thing appeared to himself, describing the facts with scrupulous accuracy, putting down the arguments as they were arrayed before his own reason, and leaving on the students an impress, sometimes strong, sometimes feeble, according to the nature of the material, of the working of his own mind. In this way it came to pass that his hearers, often unknown to themselves, not only acquired that superficial knowledge of physiological facts and doctrines which will pass muster at an examination, and serve other similar subsidiary purposes, but also acquired the art of physiological reasoning, and caught the true spirit of physiological judgment. And this I take to be the true end of all physiological teaching for the medical man—training of his mind into good habits of physiological criticism, the building up of a physiological judgment. As we all know, each learning has its own logic—to think in chemistry is not the same thing as thinking in biology. A man may be an accomplished mathematician, or a profound theologian, or a great scholar, and yet may speak words of foolishness when he goes out of his way to pronounce opinions on biological problems. In order to pass a sound judgment on the phenomena of living beings, a man must have become familiar with these phenomena, and have accustomed his mind to the workings of their problems.

The value of physiology as a study preliminary to practical medical education is not, I would venture to urge, to be gauged simply by the consideration that a knowledge of broad physiological facts is a necessary antecedent to any intelligent comprehension of the nature of disease and the rules of the medical art, important as that consideration may be.

Something of more value than a bare knowledge of facts may be gained by adequate physiological teaching, the formation of the physiological mind, which, if there be any force in the arguments I have advanced to-day, is also the pathological mind.

But it is obvious that, if this view of physiology be admitted, the teaching of physiology must not be confined to the mere didactic exposition of the more generally received dogmas, to the thumbing of some physiological horn-book. The student must be brought face to face with the problems of the science, and be trained in the method of their solution. And from this point of view, these discussions and controversies and speculations, which are often made a reproach to physiology, have a value of their own.

If physiology be considered as mere positive knowledge of direct practical utility, it may seem a waste of time that the student should spend any days of the few months at his disposal in such recondite or disputed matters as the phenomena and nature of a nervous impulse or a muscular contraction, the action and reactions of vaso-motor machinery, the molecular changes of the secreting cell, and the like.

But the question assumes a different aspect when the teaching of physiology is looked at from the point of view of training. The problems involved in the matters of which I have spoken are types of the pathological problems with which he will have to deal in after-life, and the solution of which will determine his practice for the better or for the worse. By being trained in ways of physiology, in which the materials for observation are ready at hand, and experimentation comparatively facile, his mind will become moulded to a just and critical appreciation of pathological doctrines; he will have put into his hands, so to speak, an intellectual sieve, by which, even in after years, he will be able to sift the chaff of medical literature from the grain—even in after years, for the critical faculty will remain long after the facts on which and by which it was formed have grown dim to memory or vanished quite away.

Moreover, it must be remembered that the physiology which he learns in the first two years of his medical study is that which must last him his lifetime. He cannot again, in maturer years, sit day after day at the feet of the lecturer, or again work in the laboratory. The physiology which he

learns must be of the kind which will wear, and no physiology will wear which is not worked into the mind of the learner. If the student be merely taught in didactic fashion the current physiological dogmas of the day, if these be simply packed away into his memory in more or less artistic manner, with the view of easy reproduction in the examination-room, they will soon forsake him, even if he does not leave them behind him in the ordeal, liberally exchanging his physiology for his diploma, and when, in after years, he strives to grasp the physiological basis of some pathological doctrine, which demands the entire reversal of his previous practice, he will find an impassable gulf between the physiology of his youth and that which he desires to comprehend.

Whereas, if he had entered into the true spirit of physiological study, had laid hold of physiological methods, had risen to a comprehension of the real meaning and true value of physiological dogmas, he would find a genetic continuity between the doctrines of successive generations, and enter easily into even the newest conceptions of his time. Nay, rather he would promptly recognise, in the dominant teachings of the day, views familiar to him as the subject of what, in his youth, practical minded people derided as idle and transcendent speculation or profitless controversy. For physiology, in spite of the feebleness of its workers, in spite of the obstacles which block its way, and the restrictions which cripple its efforts, is a progressive science. True, it seems to be for ever casting its skin, but that very exuviation is a sign of the growth. I dare say, to some of my hearers, many of the questions which are agitating physiologists at the present day may seem idle and transcendent questions, nor would it be easy to point out the practical utility of such themes as, whether electric currents are naturally present in nerves and muscles at rest; whether, in the typical cell, there exists a meshwork continuous with the meshwork of the protoplasmic cell-body; what are the exact changes induced in proteid matter by the action of trypsin and the like; and it may seem sheer cruelty to demand that the student, into whose few years of study so many new and strange topics are crammed—a few years of study, moreover, the commercial profit of which, in after life, does not promise a very heavy percentage of profit on money invested—should be parried with these and similar questions.

And yet, not by any spirit of prophecy, but in simple reliance on the abundant analogies offered by the progress of our science, it may be safely predicted that the solutions to these questions, or to questions equally transcendent and idle in their present aspect will become part and parcel of the pathology of the future; and will, in perhaps not so very many years, help to form the equipment of the obscurest village practitioner.

But I hear some one asking, In thus demanding for the medical student larger and fuller teaching of physiology, are you not adding a new burden to a creature this long while already overburdened far too much? By no means. No one opinion do I hold more strongly than this, that our youth, not medical only, but of all kinds, having been for many years past over-examined, are now year by year being more and more over-taught; and one of the most urgent needs of medical education seems to me to be, not a multiplication, but a simplification, of medical studies. And, if a wider scope is to be given to physiology, something must be given up to afford the necessary room. Much might be done by clearing away with a bold hand the traditional encumbrances whose uselessness is acknowledged by many, if not by all. Others have argued more forcibly than I can do against the practice of compelling the student to spend precious hours in acquiring knowledge which might admirably qualify him as buyer to a wholesale drug-house, or which might stand him in good stead if it fell to his lot to settle in practice in the wilds of Africa, and against introducing into a professional examination scraps and fragments of such studies as comparative anatomy, which ought to find their place only in preliminary studies, if at all. I would, however, to-day be hardy enough to spend the few moments left to me in attacking a tradition more honoured than any of these.

I think I am not overstating the case when I say that, in the two years (or less than two years) which the medical student devotes to studies other than clinical, some 60 or 70 per cent. of his time—in some cases even more—is spent on the study of topographical anatomy. That study may be regarded in two lights—as a discipline, and as practical useful knowledge. The late Dr. Barks, in a remarkable

introductory address which he delivered at University College, London, many years ago, insisted most strongly that its value as a discipline was far higher and more precious than its direct utility; and I imagine that the more one reflects on the matter, the more clearly this will appear. The details of topographical anatomy have this peculiar feature, that, though they can only be learnt with infinite pains and labour, unlike other things hard to learn, they vanish and fly away with the greatest ease. I would confidently appeal to my audience of practical men, how much of that huge mass of minute facts, which in their youth they gathered with so much toil, remained fresh in their minds two years after they passed the portals of the college; and how much now remains to them beyond a general view of the parts of the human frame, and a somewhat more special knowledge of particular regions, their acquaintance with which has been maintained by more or less frequent operations. I would confidently ask them what is the ratio, in terms of money or any other value, which the time spent in those early anatomical struggles—say over the details of the relations of the several parts of the forearm—bears to the amount of that knowledge remaining after twenty, or ten, or even five years of active practice, or to the actual use to which that knowledge has been put.

No, it is as a discipline, and not for its practical utility, that anatomy has been so useful; and this, indeed, may frequently be recognised in the questions set at examinations. When the candidate is expected to describe, within the error of a few millimetres, the structures traversed by a bayonet thrust obliquely through the neck, or is invited to reproduce written photographs no less exact of the parts which, from skin to skin, underlie a triangle or quadrangle drawn in ink on the front or back of the thigh, it is clear that the examiner has in view, not the needs of practical life, but an easy means of testing the proficiency of the student in mnemonic gymnastics; and of its value as a discipline there can be no doubt. In past years it has served as the chief culture of the medical student—as the chief means by which the rough material coming up to our great medical schools were trained to habits of accuracy, of exactness, of patient careful observation; and their memories strengthened by exercise for the subsequent strain which would have to be put upon them by more strictly professional learning. In this aspect, the very sterility of the subject was a virtue. The mere fact that the separate details seemed to hang loosely isolated in space, held together by no theory, no ideas, inasmuch as it made the learning a harder task, increased its disciplinary value. Most wisely did the leaders of our profession insist that no trouble or expense should be spared to afford the neophyte this preparatory scientific training; and that, as far as examinations and the like can go, no pains should be spared to compel him to avail himself of the opportunities offered. Indeed, viewed as a branch of education, the machinery of anatomical instruction has for many years past been excelled by none, if it has been equalled by any.

It must not, however, be forgotten that at the time when our anatomical teaching was instituted, not only did not the student in most cases come to the hospital a raw lad, whose only chief intellectual training had been the mechanical routine of an apprentice's duties, but no other subject matter was available as a means of discipline for a moment comparable in value with anatomy. All things suffer change. Is that which was best twenty or thirty years ago to be considered always as best? Whether the student serves an apprenticeship or no the struggle for professional existence renders it every day more and more incumbent that he should, before joining the profession, receive an adequate training in physics and chemistry, whereby he gains a discipline identical, up to a certain point, with that of anatomy, for who dare deny the value of physics as a training for accuracy and patient observation, or of chemistry for equal accuracy and mnemonic practice; and when he has joined the profession he must, in addition to his anatomical studies, traverse the ground of a portion at least of that physiology which the progress of events has transformed into something hardly recognisable as the lineal descendant of physiology two generations ago. His time, in fact, in the initial years of study is divided between two chief subjects—*anatomy and physiology*. The one is a limited subject, which long ago reached perfection. For years it has been admirably taught, carefully protected, zealously defended, and its power is dominant in the council boards of the profession. The other is a broader, an almost unlimited subject, restless, fermentative, slowly, though surely, settling down

into a body of admitted proven doctrine. For years it, as a younger brother, has had little of the fruition of power; it has had to sit in the lower seat, and has too often been imperfectly and badly taught, and in a still more imperfect way examined.

It would be foolishness to maintain that physiology taught in a fragmentary, make-shift, at times injudicious manner, its study carried on in a corner, without due appliances, at scanty moments snatched from other labours, can for a moment be regarded as an adequate preparatory discipline for the complex duties of the profession. But if there be any truth in what I have urged to-day, then I would make bold to affirm that if physiology be served in the future with half the zeal with which anatomy has been served in the past, if it be taught seriously and thoroughly, if the study of physiology be allowed to mean that the student should be really made to comprehend the conclusions at which science has arrived and is arriving at concerning the phenomena of living beings, to understand the trains of reasoning which have led to those conclusions, whatever habits of accuracy and of patient observation, whatever strengthening of the mind is gained by anatomy can be gained by physiology too.

Were time long enough, and means ample enough, I would above all things desire that the demands of anatomy should be maintained with all their present imperiousness and importunity; nay, more—I would gladly make it incumbent on every practitioner that every one year in seven he should return to the dissecting-room and revive his knowledge and rejuvenate his scientific instincts by twelve months spent again in anatomical studies; but since it is clear that the grasping necessities of our time, which are unceasingly narrowing us in as the bounds of science widen, will not permit an equal and contemporary development of these two great initial studies, I would, in all respectfulness, urge that it will be in the long-run best for the profession if the present relations of the two are reversed, and anatomy made secondary to physiology.

And if what I have advanced be true, that physiology well and carefully taught (and I fully admit the immense responsibility which, in such a case, will rest on the teacher to take heed that the study is a serious one, and does not degenerate into a peep-show play with stained sections, or a tedious trifling with reagents and recorders, test-tubes and tambours) is in disciplinary worth the equal of anatomy, if we add to this the consideration that beyond all doubt the former engenders habits and strengthens faculties, which the latter does not touch—habits and faculties which are in repeated, in constant, demand in daily profession; the habit of reasoning securely on data of mixed and uncertain value; the faculty of struggling to a right conclusion out of the confusion of conflicting facts and views; and the reflection that it is possible to be a most accomplished anatomist, and yet remain in almost complete ignorance of other sciences, while physiology is so bound up with physics and chemistry that to know the one is to have learnt the others, there cannot, I humbly submit, be much doubt as to the justice of my position.

In conclusion, I feel that I owe my audience some apology for the words which I have spoken. I fear that I have taken an undue, a selfish advantage of the honourable position in which I have been placed to-day to set up my horn on high. While the only excuse which I have is a love of the science to which I have given my life, a love strong enough to raise a zeal perhaps not according to knowledge. I would also venture to remind you that we physiologists, who are every day becoming more and more separate, but who, I trust, will never be estranged from the practical callings of the profession, are a folk not only few but feeble; and I pray you not to measure the strength of our science by the paucity and weakness of its followers. Our lot is at present a hard one; outlaid by the law of the land, our chief token of blessedness is that men and women, some of them representative and distinguished, revile us and say all manner of evil against us; many even of our own brethren of science stone us, or pass us by. To ourselves there is little help: it is to you, the great medical profession, we look for aid and support; and, as our guardians, I pray you patience, for having laid before you something of our hopes and our wants.

A MEDICAL STUDENT, a son of Dr. Roughan, Local Government Board Inspector, was drowned in the Corrib last week.

ABSTRACT OF AN

Address

DELIVERED AT THE OPENING OF

THE SECTION OF PSYCHOLOGY,

*At the Meeting of the British Medical Association,
at Cambridge, August, 1880.*

By J. CRICHTON BROWNE, M.D., LL.D., F.R.S.E.,

LORD CHANCELLOR'S VISITOR OF LUNATICS.

CIRCLES OF MENTAL DISORDERS—MODERN NERVOUS DISEASES.

ACCORDING to the latest official returns there were, on Jan. 1st last, 71,191 lunatics, idiots, and persons of unsound mind in England and Wales, 9624 in Scotland, and 12,819 in Ireland, making a grand total of 93,634 persons labouring under mental diseases or defects in Great Britain and Ireland. But this grand total, we must recollect, represents only certified or officially recognised lunatics and idiots, and corresponds with an inner circle of insanity, marked off by an arbitrary and somewhat shifting line, and outside of which lies a second circle, embracing a multitude of persons who are subject to no legal restraint, but still come to a large extent under medical supervision, and cannot be shut out from any scientific survey of insanity. Within this second circle—the crazy circle, I should be inclined to call it—fall lunatics whose mental disease, although patent enough, is of so inoffensive a kind that it is not thought justifiable to interfere with their liberty; lunatics whose mental disease is concealed, and lunatics whose mental disease is of a partial character, and is not, perhaps, popularly regarded as mental disease at all. Here we have instances of incipient insanity that has not yet expanded into dimensions that are perceptible to the eye of the law, and of chronic insanity that has crept out of its range of vision, and hosts of eccentric, half-mad, crackbrained, and imbecile persons, who move about in every grade of society. No census of the population of this second or crazy circle has ever been attempted, but that it is very great may be inferred from a number of circumstances. The late Premier told us that he had to keep a capacious bag for the crazy correspondence from presumably sensible people that was constantly pouring in upon him; and the Astronomer Royal, we are informed, has a row of pigeon-holes, in which are stowed away the mad communications as to perpetual motion, the squaring of the circle, and other obscure problems, that reach him daily from unappreciated lunatics. Our courts of justice are but too often engaged in investigating crimes committed by indisputable lunatics, whose insanity was not noticed until it culminated in violence or fraud; and our coroners can tell a dismal tale of the consequences of mental disease that has never secured official recognition. There are now upwards of one thousand seven hundred suicides in England and Wales annually, and of these not more than thirty occur amongst registered lunatics of all classes; but in at least three-fourths of these one thousand seven hundred suicides, as appears from evidence given at the inquests, there were distinct signs of mental unsoundness preceding, often for considerable periods, the act of self-destruction; and, as suicide is but the crowning expression of melancholia of a certain intensity, and is only resorted to by a small percentage of those who suffer from mental dependency, the fact that not fewer than one thousand three hundred suicides of unregistered insane persons take place in England and Wales yearly reveals great unfathomed depths of mental unhealthiness in our community. And the experience of medical men also points to vast reserves of hidden and unauthenticated insanity. Of the patients whom they are called on to certify insane a large proportion have been more or less mentally deranged for months, or even years, before the date at which legal or medical intervention is deemed requisite; and of the patients who seek their advice for merely bodily ailments a certain number prove to be unmistakably mad, even when they are figuring as useful members

of society, and are unsuspected, save by their nearest relatives, of any mental taint.

With the view of obtaining an approximative estimate of the contents of the crazy circle, I some time ago asked a few of my friends, both lay and medical, to scrutinise for me their own acquaintance, and to jot down, firstly, the number of acknowledged lunatics within that acquaintance, whether in asylums, boarded in private houses, or at home; and, secondly, the number of individuals included in it who, although not certified or acknowledged lunatics, are still held in general estimation to be *non compos mentis*—eccentric or half mad. Well, the result of that inquiry was that, within its range, the half mad were to the mad as two to one; from which we should have to conclude that there are at the present time upwards of 180,000 occupants of our crazy circle in the United Kingdom. Now, I am not inclined to adopt or defend that computation, nor to attach undue importance to an inquiry so trivial in character and so beset with sources of fallacy. I only refer to it as affording some corroboration of the belief that there is much unrecognised insanity in the country, and that the crazy circle is densely populated.

But if we had summed up all the constituents of the crazy circle surrounding the circle of recognised insanity, we should still not have exhausted the material with which medical psychology is concerned; for beyond the crazy circle there lies another and an outer circle, which may be named neurotic, and in which are assembled the sufferers from all forms of nervous disease that are not necessarily accompanied by mental disorder, but that must be placed in the same category with insanity, and that in many instances tend towards it. These are epilepsy and paralysis, locomotor ataxia, and every sort of spinal mischief, neuralgia, hysteria, chorea, and, indeed, the whole order of nervous diseases, which, it need scarcely be said, are widely prevalent amongst our population. The returns of the Registrar-General, which are unavoidably most imperfect on this point, show that nearly 70,000 deaths are attributed to nervous disease in England and Wales each year; and as these diseases are not all acute in their course, and are sometimes much protracted, this rate of mortality betokens that the number of persons afflicted by them and living at one time must be very considerable.

In the three concentric circles that I have enumerated, the insane, the crazy, and the neurotic interchange, and circulation is of course perpetually going on. They are incessantly agitated by centripetal and centrifugal and rotatory currents. A person who has been simply neurotic becomes suddenly insane, and rushes into the central circle; a certified lunatic recovers partially, and, being emancipated from restraint, steps into the crazy circle; and a crazy being, with occasional acute exacerbations of his craziness, requiring temporary asylum treatment, oscillates between the crazy and the insane circles. And, as I have already hinted, these circles are not sharply demarcated from each other. On the contrary, the whole mass of mental and nerve disease is finely gradated from the centre to the circumference, and the lines enclosing the circles into which it is for convenience divided are drawn in an arbitrary manner, and are not by any means fixed and immovable. Hence the difficulties that arise in determining whether the contents of any of the circles are increasing or diminishing, for the shifting of the containing line in the slightest degree would obviously altogether vitiate any comparison of the quantity of the contents of any two circles at two periods, one before and the other after the shifting. With reference to the insane circle, it is alleged that its radius, which is really the definition of insanity, is of an elastic nature, and has been stretched in modern times so as to comprehend much that formerly belonged to the circle of craziness. And thus an explanation, that will not seriously alarm us, is offered of the startling fact that the number of our registered lunatics and idiots has nearly doubled itself in the last twenty-one years, having increased from 37,762 in 1859, to 71,191 on the 1st of January last. Under the influence of the lunacy laws, we are told, and of a more liberal popular conception of insanity, a considerable belt of what was formerly the crazy circle has been annexed to the insane one; and this annexation, together with the enlargement of all the circles in proportion to the increase of the population, will account for its strangely increased dimensions and for the enormous increment of lunatics and idiots with which we have now to deal. For my part, I am not able to credit this flattering tale, nor to perceive any proof that the definition of insanity has been

extended in the manner alleged; but I cannot pause here to examine this vexed and entangled question by the old methods. I desire rather to call your attention to the dimensions of the outer, or neurotic, than to those of the inner, or insane circle; and in doing so, I may, perhaps, throw some light on the dispute as to the real or fictitious character of the enlargement of the latter. For probably a certain proportion is maintained between these two circles. Many nervous diseases lead up to and eventuate in mental derangement, and the *neuroses* of one generation are not rarely the *insanias* of the next. We should expect, therefore, that any marked increase or diminution in neurotic affections would be followed, after a time, by a corresponding rise or fall in the rate of prevalence of affections of the mind.

Well, the fact seems to be that neurotic affections are increasing and multiplying on every hand. Dr. Beard, an American physician, who has studied the subject with much ability, maintains that an entirely new state of the system, a morbid nervousness, unknown to the ancients or to the fathers of medicine, has developed itself amongst his countrymen during the last half century. This state declares itself in neuralgia, sick-headache, dyspepsia, hay-fever, and, above all, in neurasthenia or nervous exhaustion; and Dr. Beard appears to think that this it is that has set its stamp upon bodily configuration—making the Americans taller, thinner, and lankier than their original stock in England and Germany. The indications which he adduces of the unprecedented nervousness of the inhabitants of the United States, when that nervousness has not mounted into actual disease, are their increased sensitiveness to cold and heat, rendering them unable to live with comfort in rooms of a temperature lower than 70° F., their greatly augmented susceptibility to the action of stimulants and narcotics, the customary doses of which have had to be universally reduced in modern times, the premature decay of their teeth, and their utter inability to digest pork, which their grandfathers partook of in large quantities with impunity. From his own observations, and from the information which he has obtained from old and experienced physicians, and from medical literature, Dr. Beard unhesitatingly concludes that all nervous diseases are on the increase in America, that many bodily diseases are assuming a nervous or asthenic type, and that nervous exhaustion is so common that it must be regarded as a distinct disease of which there are several varieties.

In this country nervousness has not certainly obtained the ascendancy that it is represented by American physicians to have secured at least in certain districts—notably in the Northern and Eastern States—on the other side of the Atlantic. And yet we are not without evidences that nervousness—that is to say, the nervous temperament and diathesis—are much more common in these islands than they used to be, and that in some respects we are approaching the state of matters that exists in America. It has even been maintained that in bodily habit our people are visibly adopting the style of Brother Jonathan, and that fat people are less numerous, and thin people more numerous, in the well-fed classes of society, than was formerly the case. Allowing, it is said, for the effects of changes in diet, and for the deceptions which changes of costume, like that from crinoline to tying-back and jerseys, may create, it is still manifest that our nation is growing thinner as a whole, and that plumpness is giving place to elegant attenuation. I dare say many of us recollect Hawthorne's description of a middle-aged Englishwoman as she appeared to him in 1863. "She has an awful ponderosity of frame," it ran; "not pulpy, like the looser development of our few fat women, but massive, with solid beef and streaky tallow, so that (though struggling manfully against the idea) you inevitably think of her as made of steaks and sirloins. When she walks her advance is elephantine; when she sits down it is on a great round space of her Maker's footstool, where she looks as if nothing could ever move her." That was a coarse and ungracious caricature to come from a pen, usually so dainty and kindly, as that of Hawthorne; but it would, I think, give comparatively little offence if published now, compared with the storm of indignation that greeted it at the date of its appearance, and simply for the reason that there would be less truth in it. Very stout women, even middle-aged, are, I fancy, less frequently met with than they formerly were; while our young women, although, happily, far from rivalling the slimness of American girls, are, on the average, probably thinner than their grandmothers were at the same age. If this is so, we can only

attribute the change which has taken place to the influence of the conditions of modern life upon the nervous system, and through the nervous system upon the nutrition of the tissues. The female sex is of nervous temperament as compared with the male sex, and Laycock used to say that feminine and nervous were synonymous terms. It is, therefore, in women that we should expect to find the earliest and most marked manifestations of changes in the nervous system, influencing nutrition, like those just alluded to, and also of changes establishing greater susceptibility in sensory perception, which has also been pointed to as a sign of the growing nervousness of the age. Our refined and nicely discriminating nerves, it has been asserted, cannot, without discomfort, endure the strong impressions that give to coarse nervous organisations only an agreeable stimulus, and hence the substitution in modern decorative art of delicate combinations and neutral tints for the glare of primary hues—orange, and red, and purple—which were in vogue in days less nervous than ours.

All this, however, is somewhat problematical, and we are not without more definite proofs that nervousness is increasing amongst us. What might perhaps be regarded as the best of all proofs of that proposition—an increase in the rate of mortality from nervous diseases, the results of nervousness—cannot be adduced in its support, for the returns show that nervous diseases, as a whole, were as fatal twenty years ago as they are now, and that the number of deaths ascribed to them has fluctuated very little from year to year. But it is to be borne in mind that the death-rate from nervous diseases, as officially set forth, is but a fallacious guide to any estimate of their prevalence, for a large number of the victims of nervous disease succumb to intercurrent maladies, which are registered as the causes of death; and nervous diseases might be disseminating themselves widely amongst us, while nothing in the death-rate gave token of the process. Then analysis of the return of deaths due to diseases of the nervous system reveals that while that return, as a whole, has undergone little change, very remarkable changes have taken place in the items of which it is made up. A great reduction has taken place in the number of deaths ascribed to "convulsions," a term which used to cover a multitude of infantile ailments—many of them not nervous at all—and which is still too indiscriminately applied, while a compensatory augmentation has taken place in the number of deaths ascribed to other and less obscure diseases of the nervous system, about which there could be no mistake. As, then, owing to increased care and skill in diagnosis, a large number of deaths which were formerly improperly classified under diseases of the nervous system, are now classified under other headings, and as, notwithstanding this, the death-rate from diseases of the nervous system remains the same, we are entitled to conclude that there has been an increase in the death-rate from nervous diseases, although this is not apparent on the face of the return.

It is not, however, in connexion with the death-rate due to diseases of the nervous system themselves that the increasing nervousness of this country is most clearly evinced. That comes out most distinctly in connexion with the prevalence of other diseases not called nervous, but containing a powerful nervous ingredient. In diabetes the nervous system plays an important part, and the highest authorities are agreed that it is often brought on by mental anxiety and distress, or by sudden fear and shock. Well, diabetes is advancing with rapid strides in this country. In the year 1863 it caused twenty-seven deaths in every hundred thousand persons living; in the year 1878 it caused forty-three deaths in every hundred thousand living, having advanced steadily year by year in the interim. Dr. Pavy, who speaks from a unique experience, and with unsurpassed insight, is satisfied that these figures cannot be explained away by supposing that there is a more painstaking search for, and a readier recognition of, the disease nowadays than of yore. He believes that the disease is decidedly more common than it was, and he attributes its greater prevalence to the increased wear and tear of these times. Kidney diseases, including under these nephritis and Bright's disease, have also advanced rapidly in recent years, having caused 338 deaths in every hundred thousand persons living in 1878, against 215 in the same number living in 1863; and in kidney diseases, we are now taught to believe, conditions of the nervous system are often involved. Dr. Clifford Allbutt has shown that mental worry is the chief cause of granular kidney; and, Dr. George Johnson, while not agreeing with Dr. Allbutt on this point, holds that there is a real etiologi-

cal relation between mental anxiety and some cases of albuminuria, and that mental emotion often aggravates chronic renal diseases. Heart diseases are year by year advancing all along the line, and particularly in their neurotic wing. They caused 909 deaths in every hundred thousand persons living in 1863, and 1373 deaths in every hundred thousand living in 1878; and the movement must be traced, in part at least, as Dr. Quain has pointed out, to the operation of the conditions of modern life, through the nervous system, upon the organs of circulation. The deaths due to aneurism, which in my experience is as much connected with mental as with physical strain, have increased in proportion to the deaths from heart disease. Rheumatism, in which there is unquestionably a nervous element, and gout, the neurotic character of which has been ingeniously vindicated by Dr. Duckworth, are both much more fatal than they were twenty years ago.

But without any increase in the death-rate from diseases in which there is a nervous element, or from nervous diseases themselves, it is still possible that the latter might be multiplying amongst us in a disastrous manner. For there are diseases of this class which do not shorten life. They cause chronic invalidism; they cripple power, and mar usefulness; they spread wretchedness around; they embitter existence; but they do not curtail it. Indeed, it might be argued that a few mild types of nervous disease are favourable to longevity, by imposing on those whom they afflict a strict regard to health, by withdrawing them from participation in pursuits that are beset with risks, and by creating a state of system that is indisposed to acute inflammatory attacks. Many observant medical men are of opinion that cases of the minor nervous affections, about which no statistics are available, of hysteria and fidgets, herpes zoster, and urticaria, writers' cramp, and sick headache, are now studded over practice with a profusion that was formerly unknown. Premature baldness is far more frequent than it used to be. Early decay of the teeth occurs in the rising generation with painful frequency. Annual holidays have become a necessity instead of a luxury. A new literature of neurology has sprung up of late years. New hospitals dedicated to the treatment of nervous diseases have been established; a new set of specialist physicians have adopted that line of practice. The consumption of neurotic remedies, of morphia, hyoscyamus, conium, chloral, the bromides, arsenic, strychnia, and gelseminum, is enormously on the increase, as is also the consumption of neurotic beverages like tea and coffee, and of that great nerve sedative, tobacco.

These facts and considerations, and many more of like import which might be placed before you did time permit, seem to warrant the inferences that nervousness and nervous diseases are increasing in this country, that the neurotic circle is enlarging out of proportion to the increase of the population, and that the crazy and insane circles, which draw from it the bulk of their constituents, are also probably enlarging in a manner disproportionate to the increase of population.

To inquire fully into the causes of this increase of nervousness and nervous disease would be to enter on an investigation of great interest, but of vast extent. They may all, however, be summed up under—first, the increasing complexity of the nervous system, and, second, the increasing complexity of life. Neural development is still going on in the brain. It is not improbable that that organ is increasing in size in our race, and, of course, an addition to its weight that would be imperceptible in the scales might be of profound import in relation to its functional activity. But without increasing its size the brain may elaborate its structure by putting forth new gyri, deepening its grey matter, developing new cells, and laying down new commissural fibres, to an incalculable degree; and this much is certain, that whatever their nature be, organic processes are going on in the brain, by which new impressions and new modes of action are registered and transmitted from one generation to another. Thus it is that we, who are of the latest birth of time, inherit something from all past ages—a legacy which is paid not only in wealth of printed books, in cultivated continents, in multitudinous cities, in opulence of arts, in obedient armies of machines and scientific instruments, but in the finer architecture of our brains, in the enrichment of our nervous systems, in new phases of intelligence, and even new proclivities to disease. For it would seem that subtlety of the higher nerve-centres brings with it instability, and that as brain-substance grows finer in texture, it becomes more explosive in nature.

"Intelligence," says Herbert Spencer, "is the adjustment of the inner to the outer relations." If, then, the outer relations become more numerous, complex, and heterogeneous, the process of adjustment must become proportionately more difficult and hazardous. And our outer relations have surely grown numerous, complex, and heterogeneous in modern times. Our environment has grown varied and intricate; and our environment it is that contains these conditions of modern life, which, acting upon complex and subtle nerve-centres, cause our increased nervousness and increased liability to nervous disease. On every class, and on all ages, the pressure of modern life puts a severer tension. Competition waxes keener; the struggle for existence grows more exciting; and that this struggle involves danger is certain, for statisticians tell us that annuitants, clergymen, and the well-to-do classes who have to take no thought for the morrow, live longer than shopkeepers, artisans, and labourers, who have to contend for daily bread. In this struggle men find it to their advantage to crowd into towns, and Mr. Bright looks forward to a gradual diminution of the rural, and an increase of the urban, population. Well, it is in towns that nervousness and nervous diseases most abound, their growth being encouraged apparently by the excitement of town-life, by the absence of the refining and tranquillising influences of nature, and by the relaxation of those social restraints which conduce to rectitude of conduct in villages and small communities.

Address

DELIVERED AT THE OPENING OF THE

SECTION OF OBSTETRIC MEDICINE,

*At the Meeting of the British Medical Association in
Cambridge, August, 1880,*

By W. S. PLAYFAIR, M.D., F.R.C.P.,
PRESIDENT OF THE SECTION.

GENTLEMEN,—The majority of you are doubtless engaged in the active practice of the profession in all its branches; and I may confidently appeal to you to say whether the subjects coming under this Section do not only form a large part of your daily work, but, if it be not the case, that they give rise to more anxiety, and involve a deeper sense of responsibility, than perhaps any other part of your calling. If this be so, I hope you will agree with me that it is a matter of urgent importance that sufficient attention should be given in our medical schools to the training of those who are about to enter the ranks of the profession in subjects which form so large a part of their future work. Unfortunately, there is a universal consensus of opinion on the part of those who are best qualified to judge on this point—that is, those who are responsible for the teaching of midwifery and its cognate subjects—that the present arrangements of the examining boards are lamentably inadequate for the purpose. I do not think that I am entering on topics inconsistent with the work of this Section if I say a few words on this question. It is, indeed, only by bringing the defects that exist in our present course of education as regards the teaching of obstetric medicine prominently before the profession, and thus ventilating and agitating this important topic, that any real reform can be hoped for. It so happens that those who are responsible for the arrangement of our curricula and for drawing up our schemes of examination, have themselves no practical knowledge of the subjects, and may fairly be assumed to be entirely ignorant of the enormous strides that obstetric medicine has made since they themselves were students. The General Medical Council, and the board for preparing a scheme for conjoint examination, do not contain any practitioners who are specially devoted to the teaching or practice of obstetrics. There are on these bodies many eminent surgeons and physicians, but not a single obstetrician; and it is not, therefore, surprising that our special subject should be entirely neglected. I can give you no better evidence of this assertion than the fact that in the scheme of study recently prepared by the delegates of the

various examining bodies, in which it was proposed to remodel the present curriculum, while only forty lectures, extending over three months, were devoted to the whole vast subjects of midwifery, the diseases of women, and the diseases of children, two separate courses of six months each, were rendered compulsory for what is called practical medicine and surgery; that is, the examining of urine, the use of the microscope, bandaging, and the like—all very useful, no doubt, in their way, but which it is simply ludicrous to compare for a moment to the subjects coming under the head of obstetrics. Nor can it be pleaded that this neglect in giving effect to an urgently needed reform is the result of ignorance of the requirements of obstetrics; for the strongest possible representations have been made to those in authority. In 1868 all the teachers of midwifery in the metropolis signed a memorial to the General Medical Council, setting forth how impossible it was for them to do justice to their subjects in the short course of lectures allotted to them; in 1869 a deputation from the Obstetrical Society of London waited on the Home Secretary for the same purpose, and that body has memorialised the General Medical Council twice, in 1868 and 1879, and all without avail.

Now, what is the practical outcome of the existing state of things? Of course, medical students naturally devote themselves with most ardour to those branches of education which they are led to believe are most important, and, when they find obstetrics and gynaecology relegated to a summer course, they very reasonably suppose that they can well afford to neglect them. Moreover, those who do follow the teaching of their professors with some degree of attention have only a garbled and mutilated epitome of midwifery proper presented to them; for what human being can possibly accomplish the impossible task of doing more than that in forty lectures, while gynaecology cannot even be alluded to? It is really lamentable to think of the hundreds of men who are launched into the daily work of practice with such preparation as this, and of the infinite suffering and misery which their ignorance, for which they cannot fairly be held responsible, may cause. To those on whom is imposed the impossible task of teaching midwifery under such conditions the question is of vital moment. We may remonstrate; we may disclaim responsibility; but the fact remains, that we are the men to whom the students look for instruction. And when, being men with consciences, we reflect on the risk to life and the damage to health that may follow, we cannot, I am sure, but feel it to be our duty to protest as strongly as we can. It was only the other day that the Fellows of the Royal College of Physicians, assembled in Comitia, found it necessary to complain of the ignorance of the candidates who applied for the College licence on topics connected with practical obstetrics. I have had the honour to examine for that licence, and I know that the complaint was not unfounded. But what remedy did they suggest? It is hardly credible, but it is a fact, that all they proposed was to issue a circular to the teachers of midwifery, begging them to pay more attention to the teaching of obstetrics; while at the same time they rejected a motion, proposed by Dr. Barnes, and seconded by myself, that they should recommend an extension of the period of instruction to six months. In the face of the repeated assertion of the metropolitan teachers of midwifery that they could not possibly teach their subject in the time allotted to them, such a circular was a manifest absurdity, and could have no possible effect but that of demonstrating the ignorance of those who proposed it.

I do not think that a meeting such as this can do anything to enforce the needed reform; but the opinion of the profession at large is, beyond doubt, a great power; and therefore I have ventured to trespass on your patience by referring to this topic, since it is one which must interest you all, especially such of you as have sons or relatives who are to follow your steps; and I feel confident that, if due pressure be applied, both to the examining bodies and by your individual advice to the members of the Legislature with whom you may have influence, in the new scheme for conjoint examination which must ere long become law, the due claims of obstetrics will no longer be so unfairly overlooked as has hitherto been the case.

And now, gentlemen, having ventilated a pet grievance of my own, I shall not occupy your time further by any introductory remarks on the work before us. You will, I am sure, agree with me that the Section is peculiarly fortunate in having Mr. Spencer Wells to introduce that on gastrotomy.

Only a few weeks ago he performed his thousandth ovariectomy; and, having accomplished that astonishing feat and won for himself undying fame as the practical father of abdominal surgery, he may well turn his energies into a new direction, and reap fresh laurels in developing a comparatively new and untried branch of operative skill. It is not to be expected that an operation requiring so much manipulative dexterity can ever be widely performed; nor are the cases in which it is even to be contemplated of anything like the frequent occurrence of those requiring ovariectomy. Still, it is a matter of primary consequence that its indications, risks, and methods should be thoroughly and closely studied; and I anticipate that the discussion about to be commenced will naturally increase our knowledge of the subject.

The second topic we have selected for discussion is of scarcely less interest, and, bearing in mind that it treats of the best means of dealing with emergencies that may happen at any moment in the practice of anyone of us, of still greater practical importance. I know of nothing in practice more trying, and more requiring cool judgment, than a sudden and severe attack of post-partum hæmorrhage. Fortunately, modern science places at our disposal means of arresting hæmorrhage and of obviating its effects, such as the injection of styptic solutions, the use of hot-water irrigations, and the hypodermic injection of ergotin and sulphuric ether, which were unknown to our predecessors, and with regard to which much remains to be learnt.

In addition to these subjects of debate, we have a superabundance of most valuable and interesting papers on questions of great importance.

ON THE ANTI-MALARIAL ACTION OF THE CHINCHONA COMPOUNDS.

By T. J. MACLAGAN, M.D.

(Concluded from p. 215.)

THE theory of the mode of production of any disease which most commends itself to us, is that which best explains the whole of its phenomena. The view that malarial poisons are minute organisms is the only one which seems to afford even a reasonable explanation of the natural history and course of the fevers to which they give rise. It is with reason, therefore, that we accept the view that such is the nature of the poisons of intermittent and remittent fever.

The chinchona compounds cure these fevers. How do they do so?

There are two ways in which the curative effects of quinine in ague may be produced: either the quinine may so act on the system as to render it insusceptible to the action of the ague poison; or it may so act on the ague poison as to deprive it of its power of affecting the system. In other words, the action of quinine is either on the system, or on the poison. Let us inquire which it is. And first let us take its action on the system.

Quinine in large doses (10 to 30 grains) possesses in a remarkable manner the power of lowering the temperature of the body when unduly elevated. How it exercises this power is not known.

It has been supposed to be due to a special action of the quinine on the nervous centres: and if we recognise the existence of a special thermic centre regulating the distribution of heat, as the vaso-motor centre regulates the distribution of the blood—a supposition in favour of which much might be said—this explanation is to be regarded as a very feasible one.

Binz thought that this effect of quinine was to be explained by its lessening the ozonising power of the blood, and so checking oxidation. All that we really know, and all that concerns us at present, is that quinine in large doses lowers febrile temperature. What we have to consider is whether or not its curative effect in intermittent fever is due to this property, or to some other and special remedial action.

In virtue of its febrifuge properties quinine has been administered in all febrile ailments. It was at one time claimed for it that it possessed the power of cutting short typhus. More recently it has been claimed for it, as for other febrifuge remedies, that it exercises a distinctly cura-

tive action in typhoid fever, and shortens the duration of that malady. But this conclusion is not supported by the evidence.

There is no proof that quinine either shortens the duration or lessens the danger of either typhus or typhoid fever, or that it exercises a distinctly curative and curtailing effect in any other form of fever than intermittent and remittent.

The point is one which could be easily proved, and would long ago have been proved had the facts been as some have stated them to be.

I have frequently given quinine in large doses in all febrile ailments. My experience entirely coincides with that of Murchison, who says, with reference to both typhus and typhoid fevers, that he had "seen no evidence that at whatever stage it was given it shortened the course of the disease or diminished its danger."

With the exception of the external application of cold, quinine given in large doses is the most powerful febrifuge remedy we possess. There is probably no febrile ailment in which it would not pull the temperature down. But in every such ailment, except intermittent and remittent fevers, this depression is temporary. While the temperature is lowered by quinine, the morbid process which constitutes the disease still goes on; by and by the anti-pyretic effect of the drug passes off, and the disease runs its course uninfluenced by what has taken place.

So it is with all the continued and communicable fevers. Quinine has no power to arrest their course. Where there is trouble or danger from mere elevation of temperature, it may do good by lowering this; but there its usefulness ceases.

In intermittent fever the case is very different. Here the quinine actually cures. It puts a stop to the whole morbid process, and all that constitutes the disease; and it does this so constantly, so speedily, and so certainly, and its beneficial effects are so lasting, that one cannot fail to see that they are altogether peculiar, and altogether different from those got from its administration in other febrile ailments. That the action of quinine in arresting the course of intermittent fever is not to be explained solely by its febrifuge properties is further shown by its power of preventing such fever. Given during the intermission, it prevents the fever from coming on. Taken regularly by those living in malarial districts, it prevents them suffering from the action of the poison of intermittent fever. It exercises no such action in any other febrile ailment.

Besides its febrifuge property, quinine possesses no other special action on the body by which its curative effect in ague can be explained. This property does not account for its remarkable power of arresting the progress, and guarding against the occurrence, of that disease. We are thus forced to the conclusion that the curative effect of quinine in intermittent fever is not to be explained by any action which that drug exercises on the system.

The only alternative view is that it acts on the poison of intermittent fever, and deprives it of its power of affecting the system. There are two ways in which quinine might deprive the ague poison of its morbid action: it might supply to the poison the second factor requisite to its propagation, and so prevent it taking this from the system; or it might simply destroy the poison. The first is extremely unlikely. Indeed, it is difficult to find anything to say in support of it, except that it is possible. It is not at all certain that such an action might not be accompanied by considerable disturbance. But even if it were not, it could scarcely result in a cure of the disease. It would simply lead to the continued development of the ague poison during the whole period of the administration of the quinine, and to an outbreak of the disease when the drug was stopped. For the large quantity of poison which, on this view, would necessarily exist in the system at that time, would find there the material necessary to its growth and propagation, and consequent morbid action, just as it would have done had quinine never been given.

The view that quinine acts by destroying the malarial poison has much more to commend it. Regarding this poison, as we do, as a minute organism, there is nothing improbable in the view that quinine should exercise a destructive action on it; for we know from the elaborate investigations of Binz that quinine possesses in a remarkable manner the power of destroying many minute organisms, and arresting processes dependent on their growth and propagation.

It thus consists both with what we believe regarding the ague poison, and with what we know of the action

of quinine, that the latter should have the power of destroying the former. It is scarcely necessary to point out that the possession of this power would quite explain both the prophylactic and curative actions of quinine in intermittent and remittent fever. That such is really the mode in which quinine acts in these maladies seems to me in the highest degree probable.

We were led to consider this mode of action by the failure of the only alternative mode—viz., its action on the system—to explain the curative effects of the drug. We are led to adopt it by finding not only that it explains that action, but that this explanation consists with all that we believe regarding the nature of the ague poison, and all that we know regarding the action of quinine on minute organisms, such as we believe the ague poison to be.

But, it may be said, if quinine owes its curative effects in intermittent and remittent fevers to its power of destroying minute organisms, why is it only in these maladies that this curative power is manifested? There are many other ailments which are believed to be produced in the same way; but in not one of them does quinine have the same power of arresting the morbid process.

In the natural history of minute organisms there is no fact better established than that such organisms are possessed of specific differences, of whose existence their external form gives no evidence. Two organisms may be indistinguishable from each other by the highest powers of the microscope—so far as can be made out by such examination they are identical. But it may be found that the one flourishes under conditions which are fatal to the other. In the case of parasitic organisms this is specially observed; each has its own habitat, in which alone it flourishes, and in which other and similar organisms die.

Again, an agency which destroys one organism may have no effect on another, though the two may be apparently identical. A remedy, therefore, which cures one disease by destroying the organism which gives rise to it, does not necessarily cure all diseases owning an allied causation. Hence quinine may cure intermittent and remittent fevers by destroying the organisms which produce them, without having a similar destructive effect on the organisms which give rise to diphtheria, small-pox, scarlatina, typhoid fever, &c.

Organic poisons possessed of specific differences may have these differences manifested not only by the different effects which they produce on the system, but by the different effects which other agencies have on them.

The fact that quinine does not shorten the duration of all diseases caused by the propagation of minute organisms in the system, is no proof that it does not owe its power to cut short intermittent and remittent fever to its destructive action on the organisms which give rise to these maladies.

The fact that it does cut short these fevers is to be accepted as a hopeful indication that other remedies may be found capable of exercising a similarly beneficial effect on other fevers whose course we are now powerless to control.

It is in the recognition of this view that lies the main hope for the future discovery of remedial agencies specially adapted for the cure of various maladies which nowadays the careful physician leaves to run their natural course; knowing, as he does, that he is powerless to shorten it, and that unnecessary medication is apt to be injurious.

EXTRA-PERITONEAL OVARIOTOMY.

By W. A. MEREDITH, M.B., C.M.,

ASSISTANT-SURGEON TO THE SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.

THE following case is remarkable, and, I believe, unique, as offering an example of a completely extra-peritoneal ovarian cyst. I have myself seen but one other at all resembling it¹ in nearly three hundred abdominal sections at which I have assisted; and Mr. Thornton's much larger experience tallies with my own in this respect. I have in vain searched through the Transactions of the Medico-Chirurgical, the Pathological and the Clinical Societies, for a record of any similar case, and none of the best-known authorities on

abdominal tumours, whose works I have been able to consult, make any mention of such a condition.

M. M.—, a delicate-looking woman, aged twenty-seven, came to me at the out-patient department of the Samaritan Hospital about the middle of May last, complaining of abdominal enlargement. She gave the following history:—Menstruation occurred for the first time shortly after her marriage, at the age of twenty-four, three years and a half ago; the flow, which was scanty, recurred at irregular intervals on seven or eight occasions during the first two years of married life, but for the past eighteen months she had seen no further signs of it. She had never been pregnant. About a year and a half ago, in the beginning of 1879, shortly after the last appearance of the menses, she first noticed some increase of size in the abdomen, and was troubled with “dragging” pains in the left side. The swelling, after steadily increasing for some weeks, suddenly began to diminish, and entirely disappeared in the course of the next few days coincidentally with the passing of a considerable quantity of clear pale urine. From this time she enjoyed her usual health until about six months previous to her visit to the hospital, when, shortly before last Christmas, she noticed that her abdomen was again enlarging; the swelling, which steadily increased, had latterly been accompanied by a return of the old pain in the left side, and further by considerable discomfort from flatulence.

On examination, I found that the abdominal enlargement was evidently due to the presence of a cystic growth.

The patient was admitted into the Samaritan Hospital a fortnight later, on June 2nd, when the following notes were made of her condition:—“The abdomen is pretty uniformly distended by an elastic, indistinctly fluctuant, tumour, which reaches upwards to about midway between the umbilicus and the xiphoid cartilage. There is no perceptible downward movement of the upper border of the cyst on deep inspiration, and palpation conveys the idea that the growth is closely adherent anteriorly to the abdominal wall. Fluctuation, which was tolerably evident when I first examined the patient a fortnight ago, is now less distinct, and with doubtful limits, owing probably to increased tension. The percussion note is quite clear over the epigastrium, and this resonance extends in the mid-line downwards as far as to the umbilicus, or rather below it. A clear note is obtained on percussion far back in the right lumbar region, but the left flank is absolutely dull. The girth at the umbilical level measures 30 in. On pelvic examination, the cyst is felt very distinctly in front of the cervix. The sound passes 2½ in., showing the uterus pressed backwards in the hollow of the sacrum, with much impaired mobility.”

The following diagnosis was made:—“Broad ligament cyst, with very broad and close attachment to the right side of the uterus, and extensive parietal and intestinal adhesions in the abdomen.”

On June 15th the patient was operated on by my colleague, Mr. Thornton. On making the usual incision in the median line midway between the umbilicus and the pubes, the tumour was at once exposed, after dividing the linea alba, and was found to be everywhere covered by loose vascular connective tissue. After vainly endeavouring to find a way into the peritoneal cavity, Mr. Thornton tapped and emptied the cyst, which he then tried to enucleate from its capsule, but unsuccessfully, owing to the extreme thinness of the cyst wall. Attempts were next made to invert the cyst by pulling upwards the deep and hinder part of the inside of the sac, in order to effect an opening through its base into the pouch of Douglas; but each attempt merely opened up successive layers of vascular areolar tissue. The uterus could be plainly felt through the cyst wall, apparently closely adherent to its capsule; and coils of intestine were also clearly distinguishable. Below the cyst could be felt a mass of small cysts and solid tissue—evidently the right ovary. No trace of the left ovary could be made out.

Having ligatured and cut away two portions of the capsule, Mr. Thornton gradually succeeded in enucleating the remainder with the contained bunch of cysts and the right ovary, until he came down upon an attachment to the right cornu of the uterus; here he transfixed and tied, cutting away the ovary, and the remains of the cyst, leaving a very short pedicle, in which was seen included the cut end of the Fallopian tube.

On examination subsequently, the parts removed were found to consist of an extremely thin-walled multilocular cyst, partly encapsuled in loose connective tissue, and having an enlarged cystic ovary closely adherent to its base.

¹ The details of the case referred to are to be found in the twenty-ninth volume of the Transactions of the Pathological Society for 1878, 145.

The patient had some slight elevation of temperature during the first three or four days after the operation, but otherwise progressed without a bad symptom. The sutures were all removed at the first dressing on the tenth day, when the wound was found perfectly healed, and she left the hospital on the twentieth day.

The details of the operation leave no doubt as to the truly extra-peritoneal nature of the cyst, inasmuch as all attempts made to open into the general peritoneal cavity, either by passing the hand upwards over the upper margin of the tumour, or by endeavouring to effect an opening through the base of the cyst into Douglas' pouch, failed entirely in effecting their object. When attempting the former procedure, Mr. Thornton came upon the cæcum and vermiform appendix completely enclosed in loose vascular connective tissue, and closely applied to the cyst wall. This condition of things was evidently due to the adhesive inflammatory action set up in its immediate neighbourhood by the rapidly growing cyst.

With regard to the question of the mode of development of this tumour, I believe the following to be the true explanation of its origin:—The cystic disease commencing in the outer end of the ovary (whether from a distended Graafian follicle or as the result of an epithelial ingrowth, it is not at present my intention to discuss), probably gave rise to the formation of a true ovarian cyst, lying at first encapsuled in the cellular tissue between the layers of the broad ligament. In the subsequent course of its growth this cyst, distending the layers of the broad ligament, continued to develop in the direction of the least resistance—viz., more or less directly outward—until having reached the seat of reflection of the parietal peritoneum, it gradually opened up the layer of subperitoneal cellular tissue which lies beneath the transversalis fascia lining the abdominal wall, and thus came to constitute a truly extra-peritoneal tumour.

ON SCLEROTOMY.

By C. BADER,

OPHTHALMIC SURGEON TO GUY'S HOSPITAL.

CONTINENTAL oculists, especially De Wecker of Paris, restrict sclerotomy to certain forms of glaucoma. In course of time the operation will, I believe, be adopted in every case of glaucoma. Already von Graefe has been struck by the favourable course of iridectomised glaucomatous eyes with a cystoid cicatrix.

When iridesis was the fashion, leakage of the aqueous chamber beneath the conjunctiva and decrease of tension was one of its undesired consequences. Many sclerotomised patients state that excitement, sleepless nights, grief, &c., which before the operation produced hardness of the eyeball and obscuration of sight, since the existence of staphyloma of the conjunctiva (leakage after sclerotomy) gives rise to a sensible increase of staphyloma, but no more to obscuration of sight.

If, a considerable time after the operation, a vascular zone surrounds the base of the staphyloma the prognosis is not so favourable. De Wecker and others do not make a sub-conjunctival sclerotic flap. It seems to me that the more we secure a staphyloma of the conjunctiva, and through it a leakage of the aqueous chamber, the better. No repetition of the operation will be required if leakage exists.

The incision through the sclerotic should be made close in front of the insertion of the iris, whether the iris be in contact with or adherent to the cornea, or in its normal position, or displaced backwards. Our knife should be guided by our knowledge of the place of insertion of the iris in health; whether the iris be cut through or be displaced beneath the conjunctiva, no heed need be taken, provided the sclerotic be divided in front of the insertion of the iris.

Cases in which the iris had been perforated during sclerotomy seem to recover more rapidly than others; cutting too far backwards through the ciliary region may lead to shrinking of the eyeball.

An important point in the after-treatment is to explain to the patient the necessity for binding up the eyes without exercising pressure upon the eyeball. A soft, black silk

bandage suffices, it gives the patient a sense of security, and excludes light.

Case of Dr. Henry Pain of Cardiff (published with his permission).—Dr. Pain, aged sixty-three, consulted me on Oct. 6th, 1879, for glaucoma in both eyes. He had previously been seen by other oculists. Right eye: tension + 1; bare perception of light with nasal portion of retina; optic disc whitish, apparently swollen; the retinal veins full in the disc and retina; cornea clear; good aqueous chamber; pupil somewhat dilated; fixed media slightly turbid.

Left eye: tension + 2; retina sensitive to light throughout; optic disc deeply cupped, pink; retinal vessels very thin in the disc and displaced; spontaneous pulsation; remainder like right eye.

The patient, highly myopic, had suffered five years ago from albuminuria. I advised sclerotomy at once. On Oct. 10th the doctor consented, and both eyes were operated on under the anæsthetic. The eyes were kept shaded without pressure upon eyelids. He left London Nov. 13th, with good leakage and tension below par.

April 19th, 1880: Tension below par; corneæ clear; pupils drawn upwards; left iris well pushed into the bulging conjunctiva; media clear; optic discs pale-pink, flat; no trace of cupping—i.e., no trace of displacement of retinal blood-vessels in their course across the disc. Perception has returned to the entire right retina, and even large objects can be recognised.

Left eye reads well without glasses No. 2½ of Snellen's type at four inches.

Finsbury-circus, E.C.

A CASE OF

FATAL ULCERATION OF THE DUODENUM, PRODUCED THROUGH SCALDING BY HOT WATER USED AS A HÆMOSTATIC.

By J. R. GREENWOOD, M.R.C.S.

In February, 1880, I was consulted by J. H—, aged forty, a commercial traveller, relative to an epitheliomatous growth on the penis, which he stated had first made its appearance some two years before, since then he had suffered considerable pain. The glans and prepuce were now completely lost in a large mass of ulcerated warty granulations, which constantly discharged a thin sanious fluid, having a most offensive odour. There was very slight glandular enlargement, and the patient experienced little, if any, difficulty in passing his water; he stoutly denied ever having had syphilis, but owing to the presence of some very suspicious scars on his legs and thighs, I felt much inclined to doubt his statement. I strongly advised him to let me amputate the penis before the growth should have invaded any more of its substance, but it was some weeks before I could obtain his consent.

On the 29th of March, the patient being brought fully under the influence of bichloride of methylene, administered by my father, I amputated the penis about an inch beyond the pubes in the usual manner, leaving the urethra projecting slightly beyond the dorsum. The patient passed a good night after the operation, and when I saw him the next morning was in a very satisfactory condition. During the morning, however, I was suddenly summoned to him, and when I arrived found him bleeding profusely from the wound; as he was rapidly becoming collapsed, I despatched a messenger to my surgery for some perchloride of iron, and in the meantime endeavoured to check the hæmorrhage *secundum artem* by cold water and vigorous pressure. When the perchloride of iron arrived I found—as has usually been my experience with this much-vaunted styptic—that it was of absolutely no avail in checking the hæmorrhage. Matters had now reached a crisis when it suddenly occurred to me to employ the method advocated by Mr. Keetley, of St. Bartholomew's Hospital, of sponging the bleeding surface with hot water; I did so, and in a very short space of time had the satisfaction of seeing the bleeding entirely cease.

My pleasure at this fortunate result was destined to soon change into a feeling of anxiety, for when I visited

my patient at night he complained of great pain and uneasiness in the part, which decidedly wore a very unhealthy appearance. The next day I found that he had passed a very bad night, a hypodermic injection of morphia which I had administered the previous evening having afforded him very little relief, whilst one or two small sloughs had made their appearance on the surface of the wound. When I dressed the parts again at night the prognosis was still more grave, for the sloughs had greatly extended, and now threatened to involve the remains of the penis. Early next morning I was sent for in a great hurry, as he had been suddenly seized with acute pain in the abdomen with vomiting. I found him with feeble pulse, cold extremities, anxious countenance, and temperature 101° F. The bowels were also confined. As the vomiting was persistent I gave him an effervescent mixture with hydrocyanic acid and ammonia, also castor oil to relieve the bowels. When I called again towards the evening peritonitis was evidently present, although there was complete absence of the characteristic drawing up of the knees. The bowels were still confined, and I twice used turpentine enemata to relieve a distressing tympanites which, from its amount, evidently interfered with respiration. The sloughs had now extended to the scrotum and skin over the pubes. Temperature 102.5° ; pulse 130. The next morning I found that he had had no sleep owing to the intense pain, vomiting still continued, and the peritonitis was well marked. Temperature 105.8° ; pulse 148. I now began to suspect some intestinal lesion (probably obstruction), and consulted with my father as to the best course to take; we eventually decided to operate for the relief of the supposed obstruction without delay, as the patient was now (3.30 P.M.) in a very precarious condition, the temperature having steadily risen to 106.3° . On returning to the patient's house half an hour afterwards to perform the operation we found that he was just dead. It appeared that he had suddenly started up in bed a few minutes before, gave a kind of gasping shriek and fell back dead.

With some considerable difficulty I obtained permission to make a post-mortem examination, and on opening the body forty-eight hours after death the appearances were as follows: Heart hypertrophied, weight 18 oz., valves healthy; firmly adherent pale clots in all the cavities and extending into the great vessels. Lungs much congested and cedematous. Bronchial mucous membrane red and thickened. On opening the abdomen a large quantity of opaque greenish stinking fluid escaped; a large pale clot was seen lying near the duodenum, on pulling which aside a rent through the peritoneum was discovered, near the head of the pancreas. On opening the duodenum a deeply-indented elongated ulcer with a well-defined margin, about an inch long and half an inch broad, was seen. It commenced half an inch from the pylorus, the gastro-intestinal mucous membrane being otherwise healthy. All the coats of the intestine were destroyed, so that the pancreas formed the base of the ulcer, whilst the pancreatico-duodenal artery, from which the clot proceeded, was distinctly seen crossing it. The visceral layer of the peritoneum was everywhere vascular and opaque, the parietal layer being coated with soft lymph. The rent into the peritoneal cavity was close to the margin of the ulcer, and doubtless took place when the patient shrieked out immediately before death, since none of the contents of the duodenum had escaped. The liver weighed over five pounds, and was gorged with bile. Spleen large and soft. Extensive granular degeneration of both kidneys was present. From the condition of the penis and scrotum it was evident that had the patient survived a short time longer they would have entirely sloughed away, leaving the pubes completely denuded.

The patient's wife was positive that up to the time of seizure he had never complained of any abdominal uneasiness, and the question therefore arises, To what was the duodenal complication attributable? From some hitherto unexplained cause *burns* often occasion duodenal ulcers: now I am of opinion that my patient received as great a shock to the system as a burn would have occasioned from the scalding produced by the application of the hot water to such a recent wound; the general condition of his internal organs being, moreover, in a most unsatisfactory state to resist such a strain at the time. In the absence of all proof to the contrary, it appears to me I have good ground for assuming that scalding by the hæmostatic itself—which undoubtedly caused the sloughing of the wound—was also the cause of the ulceration of the duodenum.

A Mirror OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proæmium.

GUYS' HOSPITAL.

RUPTURED HÆMATOCELE OF THE TUNICA VAGINALIS;
INCISION; CASTRATION; RECOVERY: REMARKS.

(Under the care of Mr. R. CLEMENT LUCAS.)

The following report is from notes taken by Mr. C. J. Griffiths. The case was dressed by Mr. Marsh.

J. R—, aged sixty-three, was admitted on Dec. 9th, 1879. He was a labourer employed in gas-works, and had been a free drinker. He said that forty years ago he had a hernia on the left side, which became strangulated, and was operated upon. Since then he had worn a truss continuously. He gave a somewhat indefinite account of the previous condition of his scrotum, but it would appear from what he said that it was generally large, that it swelled at night time, and was larger on the right side than on the left. He had never been tapped.

On Friday, Dec. 5th, he felt ill and giddy, and was troubled with flatulence. On the 6th, when at his employment he perceived that his scrotum began suddenly to swell, and he was compelled to leave off work. The scrotum continued to increase in size during the whole of the next day, and on the evening of the 9th he was conveyed in a cab to the hospital, not being able to walk.

When admitted the scrotum was enormously distended, tense, and of a dark, purplish-red colour. The swelling was about the size of a man's head. Mr. Clement Lucas, who was called to see him, determined to operate at once, as there was evident danger that the scrotum might slough. Chloroform having been administered, an incision six or eight inches in length was made from the neck to the base of the scrotum. A large quantity of blood was found extravasated into the cellular tissue of the scrotum, after which the tunica vaginalis remaining distended behind was carefully incised. The vaginal sac was found greatly thickened, in parts atheromatous, and contained calcareous plates. Its cavity was distended by old and recent blood-clot. An attempt was then made to dissect away the thickened and degenerated tunica vaginalis, but this being found impossible, the testicle with its coverings was removed after a stout ligature had been applied. The operation was performed under carbolic spray, and antiseptic dressings were afterwards employed.

The patient suffered very little from the effects of the operation. His temperature remained normal until the 12th, when it rose in the afternoon to 101° F., but soon fell again to normal.

He went on satisfactorily with the exception of a little constipation, and on the 22nd the wound had a healthy granulating surface, with slight discharge.

On Jan. 7th the patient was allowed to get up for a short time. His general health was good. He ate and slept well, and his bowels were regular.

By Feb. 4th the wound had healed, and the patient left the hospital.

Remarks by Mr. LUCAS.—This case was exceptional, and difficult to unravel clinically, but the operation served to clear up its pathology. The patient's history was scarcely trustworthy, for he at first said there was no previous swelling, then admitted that there might have been. The result of the operation proved conclusively that an old hæmatocele had long existed, and it was by the giving way of this that the enormous extravasation occurred. The original cause might have been a long-forgotten blow, or possibly it might have commenced insidiously from the rupture of a degenerate vessel. However this may be, the immediate cause of his seeking advice was more evident. A new outflow had taken place into the cavity of the tunica vaginalis, and the walls of this being degenerated, yielded to the increased

pressure, so that the blood, after distending the vaginal sac, became extravasated into the cellular tissue of the scrotum.

The treatment adopted may require explanation, and it may be questioned whether removal of the testicle was necessary. I contend that it was advisable. The patient was old and degenerate. His scrotum had been enormously distended, and contained, after incision, much blood liable to decompose. The old hæmatocele sac was of cartilaginous consistency through the greater part, and calcareous in patches. A like condition was found in the tunica vaginalis testis. To have left this sac after incising it, and turning out the clots (the ordinary operation in a young man), would have exposed the patient to great risks of sloughing, or, at best, to prolonged suppuration. I determined, therefore, to clear the scrotum of degenerate material, and place the patient in the more favourable condition for recovery. A stout ligature was accordingly placed round the cord, and the right side of the scrotum was swept of its contents. The wound was kept antiseptic, and the patient recovered without a single drawback.

ENCYSTED HÆMATOCELE; INCISION; RECOVERY.

The following case is reported by Mr. F. A. P. Knipe, and was dressed by Mr. George Flower.

T. G—, aged thirty-two, by trade a carpenter, was admitted on Oct. 19th, 1877. He was of delicate constitution, and had suffered from pleurisy and winter cough. Three years previous to admission his scrotum began to swell on the right side, and at the end of twelve months it had attained considerable dimensions. He sought advice at the hospital, and was tapped, several ounces of fluid being withdrawn. At first all seemed well, but the swelling soon recurred, and in a few months it was as large as before. He was first seen by Mr. Lucas on Oct. 18th, when a pyriform swelling was observed on the right side of the scrotum. The apex of the cone was formed by the testicle lying at the bottom of the scrotum, and the swelling expanded above that organ. The history and appearance pointed to encysted hydrocele, but the tumour was found to be opaque. As it was clearly a tumour containing fluid, it became a question whether the opacity was due to a thickening of the walls of the cyst or to the extravasation of blood into it. To determine this the cyst was tapped, when a dark-brown fluid escaped, resembling blood which had undergone degenerative change.

On Oct. 23rd the swelling had increased again since the tapping, and was now very tense, hard, and fluctuating. The patient was placed under the influence of chloroform, and Mr. Lucas made an incision into the anterior wall of the scrotum, above the testicle, and found a cyst, the walls of which were about three-quarters of an inch in thickness. This cyst was laid open, when about four ounces of a chocolate-coloured, murky fluid and clot escaped. The operation was performed under carbolic spray, and the cyst was filled with gauze steeped in carbolic oil.

Next day the patient felt ill and had great pain in the abdomen. Pulse 98; temperature 100° 3'. The bowels were confined. Ordered fifteen drops of tincture of opium and half an ounce of castor oil at once, and a calomel and hyoscyamus pill at night.

Next day he was better, but still complained of pain in the abdomen. The bowels had not acted. The wound was dressed and looked well. Pulse 100; temperature 99° 8'.

On the 26th the bowels acted and the patient felt easier. There was not much pain in the wound. Tongue furred. Pulse 84; temperature 99° 8'.

On Nov. 2nd, although the spray had been used at each dressing, the discharge was offensive. Temperature normal.

On the 10th, the wound having been allowed to close in too rapidly, it was opened up, and a drainage-tube was introduced.

The patient remained in about the same condition, but on the 26th Mr. Lucas, not being satisfied with the drainage, made a counter-opening at the back of the scrotum, and passed a drainage-tube through.

On Dec. 17th the drainage-tube was gradually withdrawn, and the wounds were now completely healed, but some thickening of the skin of the scrotum remained.

He was discharged well on Dec. 22nd.

Remarks.—Encysted hæmatocele is of less frequent occurrence than hæmatocele into the tunica vaginalis, and it is liable to be mistaken for soft-growing tumour. The previous tapping in this case was probably the cause of the extravasation into the cyst, which was situated (as usual)

above and behind the testicle. Encysted hæmatocele ought not to be mistaken for hæmatocele into the tunica vaginalis, as the position of the testicle in the former can always be made out, whereas in the latter it is obscured; but in operating I have known the position of the testis sometimes ignored, and the organ divided in two by the incision intended to lay open the sac.

The treatment adopted in this case of laying open the sac, and causing it to granulate from the bottom, is the only one that can be relied upon, for tapping is almost invariably followed by re-extravasation.

The process of cure was somewhat delayed by removing the gauze too soon from the interior of the cyst, in consequence of which the edges closed in, and pus became retained; but the re-establishment of free drainage was quickly followed by an improvement in the patient's condition, and he left the hospital completely cured.

MANCHESTER ROYAL INFIRMARY.

ANEURISM OF THE LEFT SUPERFICIAL FEMORAL ARTERY;
LIGATURE OF EXTERNAL ILIAC; HÆMATURIA;
INCISION INTO SAC; SECONDARY HÆMORRHAGE;
GANGRENE OF TOES; RECOVERY.

(Under the care of Mr. HEATH, Senior Surgeon.)

FOR the following notes we are indebted to Mr. J. Sutcliffe, M.R.C.S., late house-surgeon.

E. B—, aged forty-five, was admitted on January 2nd, 1880, suffering from aneurism of the left superficial femoral artery. His family history good. He had himself always enjoyed good health, had no syphilitic taint, had always lived fairly well, and had not been accustomed to take spirits. At his trade as a rivetter he had had to stand all day and work with a hammer weighing six or seven pounds. During the last year, however, he had been a labourer, which had necessitated the lifting of heavy weights. About four months before admission he felt an aching pain in his thigh and shortly afterwards discovered a small tumour at the site of the aneurism. The pain continued for about five weeks, when it ceased for three weeks, and then returned. During all this time the tumour gradually grew larger; in the three weeks before admission it increased in size more than it had done during the whole of the previous three months.

The tumour, which presented all the characters of an aneurism, was very large, the circumference appearing to be about fifteen inches and a half, and was situated on the front and somewhat to the inner side of the thigh two inches and a half below Poupart's ligament. Compression by means of shot bags was tried but without avail, and considering the large size of the aneurism it was decided not to persevere with it, but to proceed at once to operation. On the morning of operation his temperature, pulse, and urine were all normal.

On Jan. 16th the external iliac artery was ligatured under the carbolic spray. Very little blood was lost; the artery was tied with a silk ligature, the ends of which were cut off short. A horsehair drainage was used, and the edges of the wound were brought together with silk sutures; the mode of dressing was Lister's. The limb was enveloped in lint and flannel bandages, and hot-water bottles were kept constantly in the bed. Several doses of Battley's mixture were given during the day and night.

On the 17th the urine was black, due to carbolic poisoning, but was free from albumen. The urine still black next day, and contained a large quantity of blood. A diuretic was ordered, and by the 22nd the urine was clear and free from blood.

On the 25th his bowels were open, with the aid of an enema, for the first time since the operation. The wound was regularly dressed at intervals of three or four days.

On Feb. 8th the wound was quite healed. Pulsation had not returned in the tumour, which was only very slightly diminished in size.

On the 16th the patient complained of painful throbbings in the tumour, which was somewhat discoloured, and in which fluctuation could be detected. Temperature 101° F. Under the impression that the sac was suppurating, it was next day laid open, when three or four ounces of fluid blood and blood-clots were evacuated, but no pus. A drainage-tube was inserted, and Lister's dressing was applied.

He did well until the 25th, when at about 9.30 he felt as though something had given way in the tumour, and there was at the same time an immense gush of blood from it. A tourniquet was applied over the femoral artery above the tumour, and the hæmorrhage at once ceased. The patient became blanched, almost pulseless, and very much depressed. Twenty drops of ether were injected subcutaneously, and in about fifteen minutes another ten drops. He then revived; colour returned to his lips, and the anxiety of countenance passed away. The tourniquet was kept tightly applied for about two hours, when it was carefully slackened and left loosely upon the limb without any hæmorrhage taking place. He was kept pretty well under the influence of opium for several days. There was no recurrence of the hæmorrhage; the wound healed from the bottom, and was completely closed on May 1st. Gangrene of the toes commenced on February 29th, but did not spread beyond the two inner toes.

He was sent to the Cheadle Convalescent Hospital on May 12th.

Reviews and Notices of Books.

Elements of Chemistry: Theoretical and Practical. By WILLIAM ALLEN MILLER, M.D., D.C.L., LL.D. Revised, and in great part rewritten, by HENRY E. ARMSTRONG, Ph.D., F.R.S., Lec. Chem. Soc., and CHARLES E. GROVES, F.C.S., Lec. Inst. Chem. Part III. Chemistry of Carbon Compounds, or Organic Chemistry. Section I. Hydrocarbons, Alcohols, Ethers, Aldehydes, and Paraffinoid Acids. Fifth Edition. Longmans and Co. 1880.

FOR years past we have had no large text-book of organic chemistry, and the want has been very keenly felt. Miller's third volume was in its day sufficient for most students, but it has long been out of print, and the rapid current of discovery swept completely past it years ago.

A new edition must, of necessity, be almost a new book, and the task of preparing it was one of such labour, and required such peculiar qualifications, that few chemists would have cared to undertake it. It is very fortunate that the work has fallen into such good hands as those of Messrs. Armstrong and Groves, each of whom, in addition to his reputation as an investigator, is known as a careful and diligent student of current scientific literature.

As the title-page announces, the present volume of over 1000 pages only deals with a part of the whole subject, and a second is promised, which can hardly be smaller than the first. Some four-fifths of the present is new matter, and so complete is the change of plan that the old book can hardly be recognised. This was, of course, unavoidable, and, indeed, the arrangement originally adopted was never a good one. The modern classification is familiar to every chemist, but some sensible modifications have been introduced. The hydrocarbons may be said to form the starting-point, for the cyanogen group belongs rather to the mineral than to the so-called organic department of chemistry. The hydrocarbons are arranged in series, beginning of course with the paraffins, and with each series the haloid and nitro-substitution compounds belonging to it are included, wisely as we think. This, with introductory matter, takes us through 400 pages. Then follow the alcohols, with the phenols and carbohydrates, the ethers, the aldehydes, the ketones, the quinones, and the acids related to the paraffins and such like hydrocarbons. Towards the close of the volume we find an account of the ingenious hypothesis of Van't Hoff and Le Bel in regard to the cause of isomerism.

Altogether the book, as far as it goes, is an admirable theoretical manual, and will be simply invaluable to those who enter on the fascinating study of theoretical organic chemistry. But we cannot help noticing that the practical character of the book has to some extent suffered by the change. The experimental details are in many cases far too

brief, and some bodies of great practical importance, such as the fats, wax, and spermaceti, the drying oils, and the green resins, are very slightly noticed. In fact, theory has, in not a few cases, crowded practice out of the field. Oddly enough, we have not been able to find any account of the mineral salts of the alcohol radicals. Where, for example, is ethylic silicate?

A CHEMICAL LUNG.

ON Wednesday last, Dr. Richard Neale, in the presence of a number of engineers, including the manager of the Underground Railway, and other scientific men, gave an interesting and, as far as it went, successful demonstration of a scheme to purify the foul air of tunnels, mines, cabins, churches, theatres, hospitals, and other buildings. The proposal is, we believe, a novel one, and promises to create a new era in ventilation. Nearly all attempts hitherto made to purify the air in crowded buildings have been mechanical, and have consisted of driving out the foul air by currents of fresh air. Dr. Neale's proposal, on the other hand, is a chemical one, and is designed to destroy the poisonous gases. It is not, of course, intended to supersede ordinary ventilation by currents, but rather to act as an auxiliary. The essence of the scheme is the adoption of some simple chemical facts. As the lungs of living beings appropriate oxygen and give off carbonic acid gas, Dr. Neale proposes to make a "chemical lung" which will appropriate carbonic acid and sulphurous gases from the air containing them, without yielding any products in exchange. The air in the tunnels of the Underground Railway was referred to as a conspicuous and well-known example of impurity irremediable by mechanical means. The principal deleterious gases in this instance are carbonic acid and sulphurous gases and carbonic oxide. All these, but especially the two former, may, Dr. Neale maintains, be easily got rid of by chemical means. By mixing a solution of sulphurous acid and water in a flask, Dr. Neale made an excellent imitation of the air at the Baker-street or Portland-road station. He then added a small quantity of solution of caustic soda, and agitated the flask briskly for a few seconds, and immediately the sulphurous smell was abolished. Into the same flask a current of carbonic acid gas was next passed, so that a lighted taper introduced into the flask was at once extinguished. After a few shakings a lighted taper was again introduced and burnt with a bright steady flame, showing that the soda had taken up the acid. Similar experiments were made with solutions of caustic lime. Dr. Neale said the facts illustrated in these simple experiments formed the basis of his scheme for purifying ordinarily impure air. As regards the Metropolitan and other underground railways, the locomotive engines might, he said, be supplied with a tank containing a strong solution of caustic soda or lime, through which the smoke should be made to pass before being discharged into the outer air. By this means the carbonic acid gas and the sulphur would be eliminated. The carbonic oxide would require to be dealt with in another way, which need not now be explained. In order to attain further purification of the air in the tunnel, each train might be furnished with a truck open at both ends, and appropriately fitted with trays or other contrivances for holding solutions of lime or soda. As the train progressed air would rush through the tanks or trays, and be robbed of its carbonic acid and sulphur in its course. The proposal is as happy as it is ingenious. It further commends itself on the grounds of simplicity and cheapness. It only remains for those concerned, and we would especially indicate the directors of the underground railway and the managers of theatres, to manifest a proper public spirit, and fairly test its practicability. There should be no insuperable difficulty in putting it to a practical test. Meanwhile, we shall watch with interest any attempts that may be made to carry out the idea in detail.

THE LANCET.

LONDON: SATURDAY, AUGUST 21, 1880.

MR. HOLMES made a wise choice of his subject for the Address in Surgery at the meeting of the British Medical Association at Cambridge, whether we regard it as merely commemorating the work of FERGUSSON, or as a contribution to the surgical therapeutics of chronic disease of the knee and hip. The question discussed was the utility of excision of these joints, and Mr. HOLMES is of opinion that while "excision of the knee is one of the indispensable resources of surgery," excision of the hip may be avoided by sufficiently careful and prolonged treatment by rest, extension, &c. On the surface this opinion appears to be a contradiction; for in etiology, pathology, and course, chronic disease of the knee closely resembles that of the hip, and the treatment by counter-irritation, extension, position, rest, opening of abscesses, incision, and drainage, is far more easily applied to the knee than to the hip, while the exact condition of the structures of the joint is more readily ascertained in the knee than in the hip. Why, then, if milder measures properly carried out will obviate the necessity for excision of the hip, do they fail in this respect when applied to the knee? Mr. HOLMES replies that the prolonged illness in cases of disease of the knee has a permanently injurious effect upon the general health, but he forgets to notice this point when urging that sufferers from morbus coxarius should be kept in hospitals or under palliative treatment for many years even. Nor has the experiment been carried out in regard to the knee so notably as is the case with the hip; had it been so we believe there would have been some striking results to record. But the real point of the case does not lie here. Mr. HOLMES clearly showed that the natural ankylosis of the knee is produced very slowly, with danger, and is usually imperfect, and then a constant source of danger, while the result of excision is a rapid, firm, and serviceable ankylosis. Excision of the hip always leaves a weakened limb; at the best the patients can never stand or hop on it, while the limb after spontaneous cure is firm, very useful, and with care can be got in a natural position. It is the difference in the ultimate result of the excision of the two joints that must always make surgeons set a different value upon them. Could we by excision obtain firm bony ankylosis of the hip, the operation would be more nearly parallel to that of the knee. But we must go still further, and express our belief that excision of the knee will soon become far less frequent in our hospitals; the joint is so easily dealt with by milder means that we are sure great advance will be made in this direction. We are referring now not only to incision and drainage of the joint, but to incision and drainage of the bones; a well-planned operation which will relieve the tension in the cancelli, and allow the inflammatory exudation contained in them to escape freely is, we are confident, destined to supersede to a large extent removal of the bones. There is one very obvious fallacy in Mr. HOLMES'S statistics that we must point out: it is that

they make no mention of the number of cases of disease of joints not excised in the various hospitals selected. Thus we learn that while 89 cases of excision of the knee were performed in Guy's Hospital in five years, only 24 were performed during the same period in St. Bartholomew's. For a study of the real value of the operation we require to know what became of the cases in St. Bartholomew's Hospital that would have been excised had they happened to enter Guy's. Did they recover? What was the condition of the limb? How long were they detained from work? In what number was amputation found necessary? We cannot but quote Mr. WOOD'S very needful caution that one death from an avoidable operation more than compensates for 100 successes. Here it is that we want more information, and it is of the character that is most difficult to obtain. We trust the Committee of the Clinical Society appointed to report on excision of the hip may be able to clear some of the ground.

Of Mr. W. S. SAVORY'S address we need say but little. It was characteristic, clear, eloquent, and useful rather in calling attention to points already known, but apt to be overlooked, than in recording anything new. Of the three discussions at the Surgical Section that on the Treatment of Wounds was first in order, and should have been first in importance, but unfortunately Mr. LISTER absorbed a giant's share of the time, and rather diverted the meeting from the practical side of the question. We wish that this, like the other discussions, had been opened by one rather than by three papers; not that we could have well spared either of the three, for they were all of them valuable. Mr. McVAIL is to be congratulated on the splendid statistics he was able to present, and they thoroughly support Mr. ERICHSEN'S assertion that the antiseptic treatment has nothing new in kind of result to show, though possibly in *uniformity* of result it may hope to have when perfected. Any comparison of the results of Dr. YEO'S and Dr. FERRIER'S experiments on monkeys is vitiated by the fact that they were undertaken for totally different purposes. Dr. YEO concentrated his attention on the healing of the wound, Dr. FERRIER was absorbed in watching the results of certain brain lesions, and we must therefore accept any comparison between them with caution. But Dr. YEO'S results are so striking that they form a strong piece of evidence of the value of Listerism. The experiments described by LISTER are so simple and yet so important that the wonder is they have not been formally made before. We say "formally" advisedly, for every one of LISTON'S and BORLAND'S cases—only to name them—that healed by first intention, notwithstanding prolonged exposure to germ-laden air, was in truth such an experiment. But those who remember how often and loudly it has been proclaimed in high places that an organising blood-clot is the greatest triumph of antiseptic surgery and a totally novel fact, will be amused to hear from the distinguished apostle of asepticism that it is the most natural result in the world, for coagulating blood prevents the growth of the all-mischievous germs, and even blood serum is not a good medium for their development. Nature indeed seems well able to wage war against these minute enemies; it is only when she is handicapped by bad health, bad hygiene, or bad surgery, that she proves unequal to it. Mr. WOOD well expressed the

truth when he said that the majority of cases of operation get well without Listerism, but that it saves the lives of a small percentage, who, without such assistance, are unable to withstand the germs. In saying this we are not detracting from the value of the antiseptic treatment; to save even 3 per cent. of lives is well worth all the trouble it may entail, and it must be of service to correct the gross exaggerations sometimes propounded by the younger disciples of LISTER whose ardour is not sufficiently tempered by experience. The pretensions unwisely urged on behalf of it have really been the great hindrances to the more general adoption of the antiseptic treatment. If now we have reached this point, that living tissues, including blood-clot, are themselves powerfully antiseptic, and can further show that this antiseptic property is in direct proportion to the vitality and general nutrition of the tissues, the issue will be narrowed down to one of actual statistics, and it will remain for Mr. LISTER to show results better than those, say, of the Kil-marnock Infirmary. Mr. LISTER has stated that he has found it difficult to obtain even a hundredth part of a drop of common water free from germs, and if this be so it is evident Dr. BORLAND'S success cannot be due to absence of these ubiquitous pests. Good as are these results, however, we cannot but cling to the opinion that a system of chemical asepticism, either LISTER'S or some modification of it, will yet give a more uniform success. But in view of the latest revelations it is rash to affirm that external chemical germicides will be more efficient than means to assist or increase the aseptic activity of the living tissues themselves. The contest is definitely transferred to this field, and the issue will certainly be of great moment to surgical science.

THE important question of cephalic temperatures, and especially of the degree to which they may be taken as indicative of changes in the temperature of the brain, has lately been the subject of renewed investigations in both France and Italy. In the former, M. FRANCOIS FRANK has communicated to the Société de Biologie an important paper on the subject. His direct experiments on the thermal conductivity of layers of bone and skin of the same thickness, show that the two tissues oppose a notable, although unequal, resistance to the transmission of changes of temperature; the bone has an insulating power much greater than the skin. For instance, if the temperature on the deeper aspect of a lamella of bone three millimetres thick is raised one degree, there is no change in the temperature of the other surface, which can be recognised even with a sensitive thermometer registering twentieths of a degree. With two degrees Centigrade of elevation of the temperature of the deeper surface, that of the other side presents only a doubtful rise of $\frac{1}{10}^{\circ}$; with three degrees, $\frac{1}{5}^{\circ}$; with four degrees, $\frac{1}{4}^{\circ}$; and with five degrees, only $\frac{1}{5}^{\circ}$. With a layer of skin of the same thickness, the difference between the temperature of the two surfaces is a little less, although still very marked. How much more considerable must the difference be when two osseous and a cutaneous layers are interposed, and the elevation of temperature of the deeper aspect is only one or two degrees. Experiments on living animals confirm these conclusions. If the inner surface of the wall of the skull of a curarised dog is warmed by means of a sinuous leaden tube, introduced through a trephine

opening in the skull, a thermometer maintained in contact with the shaven skin on the exterior does not rise until the temperature of the inner surface has risen three degrees. The same is true if the inner temperature is raised by injecting water at a temperature of 106° by means of a fine syringe. These negative results, by ordinary thermometry, have been confirmed by thermo-electric observations. An elevation of one degree of internal temperature does not affect the thermo-electric apparatus on the exterior, while an elevation of two degrees causes a deviation of the needle which corresponds only to $\frac{1}{10}^{\circ}$ C. From these facts it is evident that the cerebral temperature must rise to 42° C. (107° F.) in order to cause a surface elevation of $\frac{1}{10}^{\circ}$ to $\frac{1}{5}^{\circ}$ C. What, then, must be the rise to produce a surface elevation of one, two, or three degrees, as alleged in some recent observations? How could the function of the cortical regions of the brain be maintained with a temperature so excessive, and how could such a rise of temperature be explained? Simple afflux of blood would not account for it, since in health the temperature of the aortic blood is nearly that of the surface of the brain. It may be said, however, that the working brain produces heat, just as does any other organ, and BERNARD and SCHIFF have shown that this is actually true. But the elevation in temperature of the venous blood coming from the brain amounted to no more than a fraction of a degree, and is wholly inconsistent with such an elevation as would be necessary to cause the rise alleged to have been found at the surface of the skull.

What, then, becomes of the facts recorded by such observers as BROCA, P. BERT, HAMMOND, LOMBARD, and others? All observed that the superficial temperature of the skull rose in a notable degree under the influence of certain functional stimuli. Is the observed rise to be ascribed to the elevation of the cerebral temperature, or to the variations in the superficial circulation, or to the vascular dilatation, often so conspicuous, in the superficial vessels of the head? It is certain, at any rate, that the results of pericranial thermometry must be received with considerable caution. But what is to be thought of the system of cerebral thermoscopic localisation lately brought forward by M. AMIDON, to which, and to its doubtful value, we alluded a few weeks ago? The observations of M. FRANCOIS FRANK, which we have just described, render the alleged facts of M. AMIDON scarcely worth discussion. We may, however, mention some further facts which M. FRANK brings forward against even its possibility of truth. The statements of M. AMIDON assume: (1) the independent activity of a number of areas in the cortex cerebri—an unproved assumption; (2) the production of a quantity of heat in each of these points greater than the facts mentioned above allow us to admit; (3) the ready transmission to the surface of these local changes in temperature—another point which is contrary to the experiments now described. Supposing, however, that all these assumptions are granted, M. FRANCOIS FRANK urges that it seems still impossible to admit that an elevation of temperature can be produced in a circumscribed spot in the brain, and be transmitted through the skull and skin to the surface, without being propagated to the adjacent parts of the brain. And yet this assumption is absolutely necessary to make the alleged results significant. What evidence does experiment

give upon this point? If a lamina of cerebral substance a few millimetres thick is placed with one of its surfaces upon warm metal, it will be found in a short time that the heat has passed through the tissue, and with very little loss. The brain-substance is, unlike many animal tissues, a very good conductor of heat. If a cube of cerebral substance be taken, three cubic centimetres square, and the centre of the mass is heated one, two, or three degrees by means of an injection of warm water, or by a minute tube through which water passes, each surface of the cube rapidly rises in temperature, without, however, attaining that of the centre. If, in a living animal, one of the cerebral hemispheres is warmed by a coiled tube of lead, the opposite hemisphere, examined at a distance of four centimetres from the source of heat, presents a rapid elevation of temperature. These facts demonstrate that the cerebral substance is so good a conductor that it seems impossible that an elevation of temperature produced on a given point can remain limited thereto without being propagated to adjacent parts of the brain. The precise deductions, founded on the principle that an elevation of the cerebral temperature remains so localised at the point at which it is produced that it can be recognised in the corresponding limited area on the surface of the skull, seem to fall to the ground.

The researches of FRANCOIS FRANCK receive a very interesting and timely confirmation in some observations by Professor MARAGLIANO, of Genoa, which are published, strange to say, in support of the value of the pericranial temperature as evidence of that of local regions of the brain. The method employed was to fix three thermometers upon the skull of a female subject at points at which the thickness of the bony skull and soft tissues varied from 10 mm. to 11 mm. The cavity of the skull was then filled with water at 60° C. (142° F.), the external temperature being 6° C. (43° F.). The heat of the water within the skull, ascertained by a thermometer inserted through a hole, was compared with that of the surface every two minutes for a period of three hours. The difference between the temperature in the interior and on the surface was always from 2° to 4° C.—i. e., from 4° to 8° F. After the water in the interior had cooled down to 25·7° C., the temperature of the surface being 24·4° C., warm water was substituted, so as to raise the internal temperature to 38·2° C. The temperature of the surface continued to rise for a quarter of an hour, and then had only attained a temperature of 29·8° C.—that is, that under the conditions of the experiment, the elevation of the temperature of the interior of the skull, 23° F., only raised that of the surface 9° F.

Among the curious inconsistencies of pericranial thermometry which should of itself suggest the existence of a source of error, is the average temperature which has been given by different observers, and which varies from 93° F. to 97° F. It is evident that many conditions come into play of which a very imperfect account has yet been taken. That there are variations in different parts of the head in individuals, and under varying circumstances, is unquestionable, but it seems probable that these depend rather on the conditions of the abundant blood-supply to the scalp than on changes in the temperature of the brain.

We may point out another consideration which makes the ready transmission of temperature through the skull scarcely

conceivable. The summer sun acting on the head, either directly or through a dark-coloured hat, often renders the scalp so hot that the hand can hardly bear to touch it, without any disturbance of the cerebral functions. If changes of temperature readily permeate the skull, the cortex of the brain should be similarly heated, a supposition which is quite inconceivable.

A LARGE party, consisting in part of deputations from several important towns, paid a visit of inspection on the 20th ult. to the sewage-works of the Native Guano Company, at Aylesbury. Heavy rain had fallen recently, and the torrent of storm-water which came down deranged the process somewhat, and caused it to be seen at its very worst. This, however, can hardly be regretted by the managers, as the trial, severe as it was, was not unsuccessful.

The sewage-treatment adopted at Aylesbury is the well-known A B C process. The town contains 8000 inhabitants, and we are informed that at ordinary times the sewage of this population passes through, and is treated in the works, but the tanks having been constructed for a different purpose are insufficient during seasons of flood. The greater part of the sewage was indeed passing direct to the river at the time of our visit.

As the sewage enters the works it is mixed with clay and charcoal suspended in water. The latter is a waste product from prussiate of potash works, and replaces the blood formerly used. After a short flow, sulphate of alumina is added, and the whole then passes, perfectly deodorised, through three settling tanks, whence the effluent water runs to the river. The precipitated matter is from time to time removed by pumping, partially dried by a filter-press, and afterwards more completely by artificial heat. We observed no important alteration in the process since our last visit, and it seems to have attained its final development. It has been before the public for some years, has been studied carefully, and criticised repeatedly, and we ought therefore to be able to form a fair estimate of its chances of general adoption.

To begin with, let us state the sanitary advantages of the process. They are many. The sewage is disposed of without nuisance, or possible danger to health. The effluent water is clear, free from smell, innocuous to fishes, and in every way fit to be thrown into a river, although of course unfit for drinking purposes. It is, in fact, said to be well within the standard of purity proposed by the Rivers Pollution Commissioners, and we can readily believe the statement. Then, again, and this is a point of vast importance, the process really does recover from the sewage, and so ultimately save from the sea, manurial matters of high value to the land. Finally, the works occupy but little space, a consideration often of paramount importance in neighbourhoods where land is dear.

Turning to the extremely important element of cost, we regret to find that the evidence submitted by the Company is less ample than we could have wished. The statistics of the Aylesbury experiment, which has now lasted for several years, would be very interesting, and ought surely to be published, for it is impossible to suppose that the directors do not know how much the ten tons per week of manure

which they are said to produce really cost them. We can, indeed, understand that the Aylesbury works, being intended partly for experiment and partly for demonstration, would not exhibit fairly the working cost of the process. But due allowance for the accidents of the present position could easily be made, and an estimate formed which would at any rate give some idea of the financial merits of the process.

One single estimate of the working cost of the A B C process has been laid before us. It relates to the experiments at Leeds, which appear to have been satisfactory. For this town of some 300,000 inhabitants, the chemicals used seem to have cost from £8000 to £10,000 per annum, say £30 per 1000, certainly not an extravagant amount. The working expenses are not given in detail, but they can hardly have been large, and although the effluent water was not quite so good as it should have been, it was not unfit to be thrown into an ordinary river. It is, moreover, believed that the cost of the chemicals can be reduced, which would permit the use of larger quantities with corresponding benefit to the effluent. We are inclined to think that the quantity of chemicals used at Aylesbury is much greater than at Leeds. It is evident that more detailed and exact statistics are urgently wanted.

But while we press this part of the case, we do not wish to exaggerate its importance. The sewage question is one of the utmost difficulty, and the solution which is best for one place may perhaps be practically impossible in another. In many places, perhaps in most, sewage irrigation, facilitated if possible by the diversion of storm-water, and united with intermittent downward filtration, is, we still believe, the best and most economical process. But it cannot be denied that irrigation is in some cases attended with very great difficulties, and in such cases some method of precipitation must sooner or later be adopted. Sanitary authorities have learnt, or will soon learn, that town sewage is not, as they once fondly dreamed, a valuable property, but a nuisance, the removal of which is apt to entail considerable expense. If the Native Guano Company can show that the remedy which is offered, and which is undoubtedly efficient, is available at a moderate cost, they will have no lack of customers.

We have said nothing of the inherent value of the manure obtained by the process. That it has some value is certain; that it is worth the price now asked for it is open to question. The value is easily measured, and is, in fact, the simplest element in the whole question. The Leeds Sewage Committee believe that if the manure is saleable at £1 per ton, it will pay expenses. When chemical manures rise in price, as to all seeming they must, the value, whatever it may be, will increase, and it is by no means impossible that the process may ultimately prove directly profitable.

A CIRCULAR has been issued by the committee of the East London Hospital for Children, which was a short time ago removed from Ratcliff-highway to new and specially erected premises at Shadwell, announcing the necessity of closing the institution for two months. The reason given is that "the condition of the drainage has been found, on careful examination, to be dangerous to those residing on the premises.

Annotations.

"Ne quid nimis."

DR. MICHAEL FOSTER ON PHYSIOLOGY.

ONE of the best addresses delivered at Cambridge last week was that on Physiology by Michael Foster, which we print in full in our present number; and this indeed was to be expected from the man who has created a physiological school in that city, surpassed by none in this country and in nowise inferior to any of the most renowned on the Continent. Ten years ago physiology was taught in Cambridge only so far as the opportunities afforded by anatomical lectures permitted. Those lectures were delivered by Professor Humphry, and there were probably few men who, ten years ago, knew more of the current physiology than he, or who was better able to give point and interest to anatomical lectures by applying the facts he was engaged in teaching to the elucidation of physiological theories. About this period, however, the then recent introduction of recording instruments, the delicate apparatus employed by Ludwig and his school in their experiments, together with the great advances that had been made in histology and histochemistry, all tended to make physiology a special pursuit which could no longer be followed by the anatomist, and still less by an anatomist who was chiefly engaged in studying the relations of anatomy to surgery. With great liberality Trinity College endowed a chair of Physiology, which it presented to the University at large, and with singular good fortune obtained the services of Michael Foster. The work required was by no means new to him, and it was thoroughly congenial to his disposition. He had long been assistant to Dr. Sharpey, whose loss we have recently had regretfully to notice; and like all earnest workers, he rapidly surrounded himself by a little band of disciples, who are now themselves going out into all lands to teach the lessons they have learnt at the feet of the master. It is a matter of interest, therefore, to see in what light he regards the science he has done so much to develop.

THE PENAL PROLONGATION OF THE SESSION.

It is quite possible that the very reputation of Parliament requires that the session should be prolonged as it is being prolonged. Deep observers of the times and of public affairs may be noting the imperfection and delay with which Parliament does its work, and may have come to the conclusion that some very severe remedy is called for. We are disposed strongly towards the same conclusion. Every class of the community will have a criterion of its own to apply to Parliament, and by which to test its efficiency. We certainly have one. The amendment of the Medical Acts has been more or less before Parliament for fully ten years. The nature of the amendments needed has been palpable. The profession has been remarkably unanimous on this subject. But the work is still undone, simply because the Governments of the day have gone to work with very imperfect information, and without preliminary inquiry. But though we acutely feel the imperfection and delay of Parliamentary work, we cannot deny that the remedy applied is severe and even penal. This would be only a recommendation of the remedy if we could believe that it was likely to be also effective. But to expect members of Parliament to make good laws when they are in a state of exhaustion and irritation, penned up in Westminster, when they are thinking only of getting needed rest, and breathing country or sea air, is to be rather unreasonable. To many conscientious members the prolongation of Parliament may really mean a serious strain upon their health. It is, therefore, devoutly to be hoped that ere another August, means may be devised

which will supersede this severe and penal remedy, for such it assuredly is. We entirely sympathise with those who are jealous for the honour and reputation of Parliament, and who are resolved that it shall be made efficient as an instrument. But for the sake of the earnest men in it of all parties, we point out that there are grave objections to the indefinite or requent prolongation of its proceedings.

THE NEED OF HOLIDAYS.

IN the course of his very able and interesting address, in the Medico-Psychological Section, at Cambridge last week, Dr. Crichton Browne instanced, among the evidences of increased weakness and liability to the neurotic diseases and insanity, the fact that "annual holidays have become a necessity, instead of a luxury." It cannot be denied that, either from habit or necessity, the routine worker—whether "with what he is pleased to call his mind," or that lesser combination of the intellectual faculties by which the routine business of life is transacted—has come to look for a respite from his labours once a year as one of the essentials of existence. In the days when we were young this was not the way in which the annual holiday was regarded. Those who could afford it went out of town; but their object was pleasure, not "relief," still less "recuperation," in any serious sense. Most men worked harder, though generally in a more pleasurable way, during their vacation, than throughout the rest of the year. Now the jaded creature of oppressive and exacting circumstances crawls away to "rest." His plaintive desire is to get anywhere out of the din and turmoil and "worry"—that wondrous word—of the busy world—far, far from "the madding crowd." There is something humiliating in all this. It is a feeble sort of human nature we seem to have inherited. We should like to see the question of causation fully and impartially discussed, in view of the abundantly evident fact that we have as a nation left off drinking sound-brewed ale and well-matured wines, and have taken to imbibing vast quantities of tea and coffee; weak, watery, and acid wines; rivers of mineral waters, real and factitious; and to eating, for food, the made dishes and flimsy compounds so common on the Continent. Were our grandfathers wholly wrong when they associated the courage and stature of the British shopkeeper with the roast beef and ale of old England?

THE MODERN TREATMENT OF STRICTURE.

THE able review of the progress in the treatment of stricture of the urethra during the last thirty years by Sir Henry Thompson was a fitting introduction to the discussion on that subject at the Cambridge meeting of the British Medical Association. To those familiar with the heated disputes of former times, it is striking to see such concurrence of opinion on this subject as was then witnessed. All the speakers agreed in condemning Holt's operation, which might have been less favourably considered years ago had it not been so simple an operation that the merest tyro in our art could perform it; but it was a "blind" proceeding; the surgeon did not know what he was going to do, nor could he be sure afterwards what he had done further than forcing a way through the urethra for a full-sized instrument. Internal urethrotomy is now the operation we are all to accept for intractable strictures. But there is far more to be said on this subject than was, or indeed could be, said at Cambridge. Mr. Teevan spoke of the operation as almost devoid of danger, and challenged any one to produce a case of death from it in a young man. If he will refer to our columns he will there find evidence that should make anyone hesitate to speak lightly of the risk of this procedure. An operation that may be followed by death, abscess in joints, severe hæmorrhage, sloughing, extravasation of urine, permanent chordee, repeated rigors and sup-

pression of urine is surely as serious as many of those usually called "capital," and when we hear that its beneficial results are not, and cannot be, permanent, it is evidently an operation about which enthusiasm is altogether superfluous. We opine that perineal section in one or more of its several forms will yet maintain its position as a valuable and justifiable procedure; it appears to be free from some of the objections inseparable from its rival. We welcome Sir Henry Thompson's valuable remarks on the calibre of the urethra and the curability of stricture by incision. While we fully agree in the belief that strictures are not permanently curable by incision, we think such a result may fairly be hoped for in some cases from permanent and possibly also gradual dilatation. That the treatment of stricture has improved during the last thirty years all must agree, but we doubt if internal urethrotomy is the highest attainable point; it is undoubtedly a very useful and successful operation, but neither in its immediate nor permanent results is it so good as other and milder measures. Something yet remains to be done before surgeons can be satisfied with their power to cope with this common but troublesome disease.

SUNDAY DRINKING.

A VALUABLE return, at the instance of Mr. Onslow, shows the amount of such Sunday drunkenness as comes within the range of conviction by a magistrate, which, of course, is a very different thing from the amount of absolute drunkenness. The number of convictions for being drunk on Sundays in England and Wales, with a joint population of 22,712,266, over a period of three years, from Sept. 29th, 1876, to Sept. 29th, 1879, amounted to 47,401, or 15,800 per annum. Some of our contemporaries find in the figures a rebuke for "the tall moral talk" of reformers. We certainly find in them no material for national pride. The number of convictions varies greatly in different places, and in different kinds of communities. Liverpool and Manchester have an unenviable prominence. In Liverpool alone, with its population of 493,405, there were 4721 convictions, 4381 of these being *bonâ-fide* residents. In Manchester, with a population of 351,189, there were 3282 convictions, 3066 being *bonâ-fide* residents. In the county of Lancaster, with a population of 1,318,632, there were 4227 convictions, considerably less than those of Liverpool alone, with a little more than a third of the population. Sunday drinking is much more in these towns than in London, Birmingham, or Sheffield. In the latter town, with a population of 239,946, there were but 175 convictions. It may well be that the discipline of one town is more severe than that of others, but these discrepancies are very remarkable, and may well command the attention of the several communities to which they refer.

BATHING.

IT is important to recognise that the only virtues of water as used by the bather are two—namely, its value as a cleansing agent, and as a surface stimulant. In this last capacity it simply acts as a medium affecting the temperature of the part to which it is applied, or which is immersed in it. Right views of fact in reference to this matter are important, because there can be no question that some persons overrate the uses of cold water, and run considerable risks in their pursuit of them. Every beneficial action that can be exerted by a bath is secured by simply dipping in the sea, or a very moderate affusion of cold water! Except in cases of high fever, when it is desired to reduce the heat of the body by prolonged contact with cold, a bath of any considerable duration is likely to be injurious. Then, again, it is necessary to recognise the risk of suddenly driving the blood from the surface in upon the organs. The "plunge," or "dip," or "shower," or "douche," is intended to pro-

duce a momentary depression of the temperature of the surface in the hope of occasioning a reaction which shall bring the blood back to the surface with increased vigour, and almost instantly. If this return does *not* take place; if, in a word, redness of the skin is not a very rapid consequence of the immersion, it is impossible that the bath can have been useful, and in nine cases out of ten when the surface is left white or cold it does harm. The measure of value is the redness which ensues promptly after the bath, and this reaction should be produced without the need of much friction, or the bath is not worth taking. The rubbing employed to recover the circulation lost by the bath would probably have done more good without it! Another effect of the bath when it acts properly is to stimulate the nervous system, through the vast series of its terminal fibres which are distributed in the skin. In this way also the action must be very rapid, or it is not efficacious. Unless the vigour of energy is quickly called out, the agent is useless; and if it produces either drowsiness or depression it acts mischievously, and lowers the power it is intended to stimulate and augment. Bathers should bear these facts in mind, and be warned by them not to trifle with an agency which if it is not of value is worse than useless, and can scarcely fail to do harm.

HONOURS AT CAMBRIDGE.

THERE can be little difference of opinion as to the worthiness of those members of the profession upon whom the Honours of Cambridge fell. (We print in another column the speeches of the Public Orator on the occasion.) The foreign selections—if so they can be called—were admirable. Brown-Séquard, Gross, and Donders could not be more gratified with the rare honour of receiving the honorary degree of LL.D. Cambridge, than the profession of Britain will be gratified to know that they have received it. The case is very similar in regard to those members of the profession at home who were so favoured. But we are disposed to agree with some critics who complain that there is a certain narrowness, not to say cliquism, in the principle on which English University honours to the profession have been granted. One university follows the other very much. The majority of those who received the LL.D. the other day at Cambridge had previously received the D.C.L. of Oxford; and of the twelve, no less than six are or have been members of the Medical Council. Such restrictions are apt to give the universities and the public an inadequate view of the number of men in the profession who, on account either of their scientific work or of their general culture, would do honour to the university that honoured them. Can the Universities not act save as one leads the other, or a little less as if membership of the Medical Council constituted of itself a claim to University favours?

HOSPITAL ADMINISTRATION IN INDIA.

IN an article on hospital administration in India in our impression of May 15th, we stated that the explanation of Dr. D. B. Smith, one of the officers inculpated in the charge of maladministration, was "incorporated in the official document" under review; and we conceive that that statement was fully justified, so far as we were concerned, by the terms of the memorandum. We think it simply an act of justice to Dr. Smith to bring to notice that in a letter published in the *Englishman* of July 6th he states that "the most important parts of my letter of explanation have never yet been incorporated in any public document. All I now desire is that it should be published in full, so that the press and the public may be able to say whether or not it is true that, in all respects and at all times, instead of neglecting the interests of Government, I guarded them with zealous care, strict vigilance, and absolute fidelity." We think it is

to be regretted that the Indian Government did not publish his exculpatory letter *in extenso*, when they thought themselves justified in stating that the remarks submitted by him seemed "very fully to establish the ground taken by the Lieutenant-Governor, to the effect that the expenditure had been conducted on a wasteful and lavish scale." It is difficult to understand upon what principle the explanatory letters of Dr. Chevers and Dr. Ewart were appended to the official report, while that of Dr. Smith was withheld; although it, or, as he states, only certain portions of it, were made the subject of not very flattering comment. The course taken by the authorities is the more to be regretted, because Dr. Smith, being still on full pay, is debarred by the rules of the Service from publishing his letter—a restriction which does not apply to the other two officers, who are on the retired list. We do not say that the Lieutenant-Governor was not justified in the conclusion at which he arrived with reference to the extravagant management of the hospital; but we think that when it is found necessary to pass a severe censure on an officer of Dr. Smith's standing, it would only be fair to publish with it such defence as he is able to offer. This is the more necessary when, as in the present case, the justice of the censure is called in question. We trust that the authorities in India will, in the interests of fair play, give as great publicity to Dr. Smith's letter (No. 151, of May 29th, 1879) as they have given to the comments upon it by the Lieutenant-Governor, and the censure involved in his comments.

THE ARMY MEDICAL EXAMINATION.

WE understand that Mr. G. Pollock was unable to conduct the examination in surgery during the past week, and that his duties were relegated to Mr. Haward and Mr. J. Morgan. It would be satisfactory for others besides the candidates to know that these gentlemen were duly appointed by the authorities on the advice of their official advisers. Or was Mr. Pollock left free to appoint his own substitute? And, if so, why were the duties he usually discharged alone given to *two* junior men? Was either of them unable to do it all?

In connexion with this examination a good story is told. One of the candidates, who had made a very special study of typhoid fever in certain expectation that a question would be given on it, was so entirely at a loss when he saw that "instead they asked about enteric fever," that he retired from the examination with many imprecations on his "luck" and the perfidy of examiners!

ICE IN THE COUNTRY.

RAILWAY companies are beginning to awaken to the fact that there are many enterprises open by which their receipts may be augmented. The immense traffic done in country milk, the importation of sea-water to the metropolis, the early delivery of the morning newspapers in country towns, and the improved system, adopted by some companies, of booking small parcels and hampers, are instances to the point. We would mention another enterprise which we believe would not only benefit railway shareholders, but would prove a great boon to persons living in the country at some distance from large towns; and that is the establishment of a traffic in ice at the small stations along the line during the summer months. Ice is now becoming not merely an article of luxury to be occasionally used, but almost a necessity of civilised life; and perhaps nowhere is this necessity more felt than in remote country places where the butchers and fishmongers call only once a week. Used merely for the purpose of preserving meat, fish, milk, &c., in a household of moderate size, a refrigerator with the necessary supply of ice will be found, when well managed, to be a real economy. Moreover, apart from domestic considerations, ice is now employed ex-

tensively as a therapeutic agent. And the advantages of having a supply ready at hand in case of emergencies will be found incalculable. The boon, however, of a cheap and easily accessible supply of ice is denied to the ordinary dwellers in small country towns and villages. This ought not to be the case, and if the railway companies either themselves, or by offering facilities to agents, established a traffic in ice at the small stations on their respective lines, the business would, we believe, soon become as considerable as it is in London and other large towns. The best method for establishing such business would be, we think, to attach an ice-van to the parliamentary train on each line of railway, at first on stated days of the week, till a sufficient traffic was obtained to warrant a daily despatch. A salesman would accompany the van to attend to the distribution of the ice at the various stations, and further, the van might be utilised for the conveyance of fish from the London markets, and thus meet another requirement of remote country places.

CAVENDISH COLLEGE, CAMBRIDGE.

A CONSIDERABLE number of the members of the British Medical Association were present at a lunch given to mark the completion of a new portion of Cavendish College. The chair was taken by Prebendary Brereton, supported by Earl Fortescue, and several interesting speeches were delivered. Professor Humphry observed that this College, with its low charge of £84 per annum, was restoring the University to its original ends—the service of the poor; and it was pointed out that special facilities for the study of medicine existed in Cambridge, which was open to the students of the College, so that a boy entering at sixteen years of age could leave at nineteen, with three years of the residence necessary for the M.B. completed, well grounded in the more elementary parts of his education, with the degree of B.A. and with that of M.A. in prospect.

UNIVERSITY OF DURHAM.

A MEETING of Medical Graduates of this University was held at Caius College, Cambridge, on August 11th, when a "Durham University Medical Graduates' Association" was formed, having for its objects the maintenance of the interests and extension of the usefulness of the Medical Faculty of the University, with the cultivation of social intercourse and good fellowship among its graduates.

An annual meeting will be held in the North and South alternately. The first meeting will be held at Durham in June, 1881, immediately after the Convocation for conferring degrees.

The following gentlemen were appointed officers of the Association:—President: G. H. Philipson, M.A., M.D. Vice-President: Luke Armstrong, M.D. Honorary Northern Secretary: W. P. Mears, M.B. Honorary Southern Secretary: R. H. Milson, M.D. Committee: C. J. Gibb, M.D.; W. C. Arnison, M.D.; W. Travers, M.D.; B. Fenwick, M.B.; S. K. Powell, M.B.; W. T. Tyson, M.B.

BIGELOW'S OPERATION.

SIR HENRY THOMPSON has cordially accepted the main principle contended for by Bigelow, and regards the mischief likely to be done by the residence of fragments of stone in the bladder as greater than the ill effects of a skilful but prolonged use of crushing instruments and evacuating catheters. All the speakers at the debate on this subject at Cambridge coincided in this view; but Mr. Cadge—whose opinion on this point as on all others of surgical practice will be generally accepted as second to none—hesitates to affirm that larger stones can be more safely dealt with by Bigelow's method than by Civiale's. And we are grateful to him for his caution that Thompson's recent cases do not afford evidence on this point.

Evidently a number of stones averaging only two drachms in weight are of no value in helping us to settle the limits of size of the stone for which this operation is advisable. Is the operation better than lithotomy for stones too large for Civiale's lithotripsy, or in cases where that operation is inapplicable, as where the bladder is unable to discharge the fragments? We want evidence on these points, and it is beside the mark to heap up cases of small stones successfully removed at one, or rather, we should say, at two sittings. Sir Henry Thompson's advice to regulate the size and kind of lithotrite to the particular stone is valuable, and especially opportune at a time when some would reduce the operation pretty much to a rule of thumb, and that in favour of colossal weapons.

THE FARR TESTIMONIAL FUND.

AT a recent meeting of the Executive Committee charged with the promotion of the Testimonial Fund now being raised in acknowledgment of the exceptional services rendered by Dr. William Farr, C.B., F.R.S., in the promotion of public health and statistical science, it was announced that the subscriptions already paid or promised amounted to £958 13s. It was decided that the subscription list should remain open for another month or two, and that every effort should be made to secure the substantial success of the Testimonial Fund by bringing the subject under the notice of all who are interested in the recent progress of sanitation in England.

MORE AMATEUR STARVATION.—AN OFFER.

WE are threatened with more fasting. One would have thought that for the present the world had "supped full" of fasting; but one fool begets many imitators, and the experiment of going without food for forty days seems to some people so easy and pleasant, and so sure to bring notoriety, that it is worth trying. We have received a remarkable letter, the writer of which, finding that some medical men in England still doubt the possibility of fasting forty days and nights, says that he is prepared to show them that they are wrong. He states that he fasted thirty days and nights "without the least inconvenience"—truly a bold assertion—and that he is willing at his own expense to come to England to prove it, if desired. Such a proposal is strangely misdirected when addressed to an organ of medical opinion in England.

QUEEN'S COLLEGE, BELFAST.

THE report for the session 1879–80 shows that this College continues to prosper in the number of students attending the various classes, and in the successes achieved by those trained in it at the examinations for admission into the several departments of the public service. A steady increase from year to year has been exhibited in the faculties of arts and medicine, showing that the Queen's College, Belfast, is largely contributing to the intellectual and professional education of the people of Ireland, and thus efficiently fulfilling the important purposes for which it was established. The President in his report refers in flattering terms to Dr. Thomas Andrews, F.R.S., late Vice-President and Professor of Chemistry, observing that it would be impossible to speak in too high terms of the services rendered by him to the College, and to the cause of science throughout the world.

WE have received Gibraltar papers, giving an account of the presentation of colours to the 24th Regiment, by Lord Napier of Magdala. We regret to observe that in naming the officers and men on whom the Victoria Cross was conferred for their gallant conduct at Rorke's Drift, his lordship omitted mention of Surgeon-Major Reynolds, though he included the name of Major Chard, who was not an

officer of the 24th. Had none but officers and men of the 24th been named we should have said nothing on the subject, but the omission of the medical officer, under all the circumstances, has the appearance of being something more than a mere accident; and, if so, was quite unworthy of the gallant hero of Abyssinia.

THE distinction of Companion of the Order of the Indian Empire has been conferred by the Queen on Dr. de Vry, of the Hague, for his long and valuable services in connexion with the introduction of the chinchona trees into India, and the manufacture of Indian quinine.

THE proposition to purchase land at Longcross whereon to build a new infirmary for Cardiff appears to be still in embryo. A committee, however, has been appointed to raise subscriptions with a view to carry out the proposal. The sum required is about £40,000.

DR. JOHN BEDDOE, F.R.S., has been appointed to preside over the Health Section at the approaching meeting of the Association for the promotion of Social Science at Edinburgh.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Hackney.—Dr. Tripe's report on the sanitary condition of the Hackney District for the year 1879 contains much of interest, both generally and with reference to the particular district to which it refers. The year was remarkable for a very low death-rate from most diseases, except inflammatory affections of the lungs; for low temperatures in winter and summer, and an excessive rainfall in most months, especially in summer. Dr. Tripe refers to the intimate relations that exist between a high summer temperature and an excessive mortality from diarrhoea and *vice versa*, especially in infants. He does not express an opinion regarding the precise cause or causes of summer diarrhoea, but he thinks that existing evidence tends to show that the putrefactive changes induced in organic matter by the high temperatures set up the disease. He moreover looks upon the diarrhoea as specific, and unlike ordinary diarrhoea. Microscopic examination of the contents of the traps in water-closets, and of the air in houses where summer diarrhoea was prevalent, showed in many instances the presence of bacteroid forms, and Dr. Tripe gives illustrations which seem to render it probable that the diarrhoea is caused by the carrying of these forms into the body by sewer air. We may cite the following:—"The death-returns for London since the present system of registration has been in force also point to a similar conclusion, as in 1840, when connexions between houses and the public sewers were much less common than now, there were only 452 deaths registered from diarrhoea, and during the next four years the average was only 680; whilst between 1869 and 1878 the smallest annual number was 2479, viz., in 1877, and the highest 3894, in 1871; the mean of the ten years being 3436, against 632 for the five years 1840-4. Although these facts cannot be considered sufficient to show that summer diarrhoea results from sewer-gas containing organisms finding its way into houses, yet they certainly point to the necessity for frequent flushing of water-closets and drains with some disinfectant which retards or prevents putrefactive change, especially when the summer is unusually hot."

The infantile death-rate (that is to say, the death-rate under one year of age) corresponds "with great regularity" to the mean temperature of the air and of the Thames water; and the proportionate number of deaths at all ages from diarrhoea corresponds in different months pretty closely with those of infants. In the 20 years 1860-79 there were 7 years in which the summer temperature was in defect, when the mortality at all ages from diarrhoea per 100,000

inhabitants of London was 200; in 10 summers during which it was in excess by less than 2°, the mortality was 317 per 100,000; and in 3 years when the temperature was more than 2° in excess, the mortality reached 339 per 100,000 inhabitants. "These figures," says Dr. Tripe, "show that great care should be taken in hot weather to prevent diarrhoea, especially amongst young children, by frequent washing with soap and water to ensure cleanliness of the skin, and by wholesome food, good ventilation, especially of bedrooms, protection from the sun, avoidance of excessive exercise, frequent cleansing and disinfection of the drains, and by the removal of all animal and vegetable matter in a state of decomposition from the vicinity of dwelling-houses, especially when the mean air temperature of the week is above 60·5°, and of the Thames water more than 63·5° Fahr."

Dr. Tripe has some observations on the use of disinfectants and the use ("considerable") to which the Sanitary Authority's disinfecting apparatus was put during the year. Looking to the occurrences of small-pox in the district, 35 in number, he states that "the disease, in all instances except one, was confined to one house in a street," a result which he attributes to the active disinfection, the speedy removal of the sick, or their strict isolation, and the revaccination of the inmates in many of the houses. He gives what he believes to be an instance of transference of small-pox contagion by means of a cake and a book, but the instance is worthless from the vagueness with which the fact is stated. The following example of mischief arising from food apparently in a state of putrefactive change deserves quotation at length: "In August last I reported the occurrence of numerous cases of severe diarrhoea, vomiting, and prostration from eating dripping sold by an itinerant vendor. My attention was directed to the cases by the medical attendant of two families who thought they had been poisoned by impure water. I inspected the houses and heard the accounts given by the parents, when I came to the conclusion, as the drainage and water supply were good, that the disease was caused by eating dripping bought at the door. I called, so far as I know, at all the houses where the dripping had been supplied, and found twenty-nine cases living in four streets, two at a rather considerable distance from the others. Nearly all suffered who partook of it, and there were no similar cases amongst the residents of these streets except those just mentioned. The symptoms were great prostration, severe vomiting and purging, cramp, severe pain in the stomach, great subsequent debility, and in some cases fever, lasting for several days. There was only one death—viz., that of an infant who was suckling, but who did not, it was believed, have any dripping. Another infant suffered in the same way, but recovered. The sickness and diarrhoea came on in most cases a few hours (from four to twelve) after eating the dripping, those suffering most severely who partook of the jelly. I carefully examined the dripping chemically and microscopically. It had a peculiar and faint smell, but I did not detect anything except numerous small microscopic organisms resembling monads. The symptoms corresponded very closely to those that occurred some years ago amongst numerous residents of this district who ate some sausages, and of whom one died."

Dr. Tripe enters at some length into a discussion of the vital statistics of his district during the year; but in regard to these we would simply observe that the number of deaths from zymotic diseases was the smallest in proportion to total deaths that he had ever recorded.

A point of considerable interest in the report relates to the provision of hospital accommodation in the metropolis for non-pauper cases and the definition of a pauper. Dr. Tripe is of opinion that "any person being sick with a dangerous infectious disorder, and not having a residence of his or her own, or the means of procuring one, and not having the means of providing proper medical attendance, necessities, and nursing, is a pauper, and should be removed to a hospital belonging to the Metropolitan Asylums Board; that, on the contrary, a person having a house and the money necessary to provide medical attendance, medicines, food, and nursing, is not a pauper—so that, if it were necessary to isolate such a person, he or she should, according to the Act, be removed by the sanitary authority." This definition of a pauper has been acted upon at all times by the Hackney guardians, and Dr. Tripe believes that the Metropolitan Asylums Board's statement that 90 per cent. of the persons treated during the recent epidemics of small-pox in their hospitals were non-paupers is erroneous.

Hastings.—Mr. Ashenden's report for the second quarter of the year shows a birth-rate of 29·98 per 1000 population, and a death-rate of 19·50. Except that 28 deaths were caused by measles, the report presents nothing for remark. Happy is the health-resort that has but uneventful health-reports to present.

THE HEREFORDSHIRE COMBINATION OF SANITARY AUTHORITIES: MEDICAL OFFICER OF HEALTH.

Our readers will remember that a short time ago a threatened break-up of the Hereford Combination of Sanitary Authorities was averted by the interference of the Local Government Board, and that the combined authorities resorted to this interference by passing a resolution reducing the salary of the medical officer from £550 to £400. The resolution, however, in order to give it force, required the assent of the Local Government Board, and we are glad to learn that that Board has refused its assent to so large a reduction, but expressed its approval of a reduction of £50! It does not appear why this change in the salary, which is equivalent to casting a considerable portion of the travelling expenses of the office upon the incumbent, should have been made. Moreover, the joint appointment of a medical officer of health is confirmed for only three years. The term of the appointment, as well as the modification of salary, indicate that the Local Government Board is as unsettled as ever as to the principles upon which the appointments and salaries of medical officers of health should be governed. The Hereford Combination having entered upon a new three-years' term, will have to elect their medical officer of health anew; but as Dr. Vavasour Sandford, who has now held the appointment for several years, will, we understand, notwithstanding the modification of salary, again be a candidate, we assume that the election will be a mere formality, as it is unlikely any member of the profession will, under the circumstances, contest the post.

IMPRISONMENT AND FINES FOR NON-COMPLIANCE WITH THE VACCINATION ACT.

A Parliamentary Return has just been published showing the number of persons who have been imprisoned and fined for non-compliance with the provisions of the Act relating to the vaccination of children. It is not stated over what period the return extends, but we presume that it relates to the whole period since the compulsory powers have been in force. In England the number of persons who have been imprisoned amounts to 87; fined, 3888; and of the imprisoned 14 were imprisoned for one month or above 14 days, and 73 for 14 days or a less period. In Wales no person was imprisoned, but 41 were fined. The return certainly does not convey the impression of much hardship having been caused by the operation of the Act.

ANIMAL VACCINATION.

We learn that the Medical Officer of the Local Government Board, Dr. Buchanan, has left London for the purpose of visiting several of the animal vaccination establishments on the Continent, in furtherance of the arrangements contemplated by that Department of the Government for the introduction of the practice into England.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

The fatality of infantile summer diarrhoea caused a further increase in the rate of urban mortality last week. In twenty of the largest English towns, estimated to contain in the middle of this year seven and a half millions of persons, or nearly one-third of the entire population of England and Wales, 5358 births and 3567 deaths were registered last week. The births were 173, and the deaths 292 above the average weekly numbers during 1879. The deaths showed a further increase of 138 upon recent weekly numbers. The annual death-rate per 1000, which had steadily increased from 18·9 to 23·9 in the six preceding weeks, further rose last week to 24·8. During the past six weeks of the current quarter the death-rate in these twenty towns has averaged 22·0 per 1000, against 25·5 and 17·7 in the corresponding periods of 1878 and 1879. The lowest death-rates in the twenty towns last week were 15·8 in Wolverhampton, 16·6 in Bristol, 17·1 in Portsmouth, and 23·0 in Bradford. The rates in the other towns ranged

upwards to 27·7 in Sunderland, 27·8 in Liverpool, 29·0 in Leeds, 33·3 in Leicester, and 37·6 in Salford. The high death-rates in these last-mentioned towns were mainly due to excessive diarrhoea fatality.

The deaths referred to the seven principal zymotic diseases in the twenty towns, which had steadily increased from 406 to 996 in the nine preceding weeks further rose to 1100 last week. These included 807 from diarrhoea, 112 from scarlet fever, 62 from whooping-cough, 54 from measles, and 44 from different forms of fever. The annual death-rate from these seven diseases averaged 7·7 per 1000 in the twenty towns; while it was but 2·1 and 3·9 in Wolverhampton and Bristol, it ranged upwards to 14·1 and 15·2 in Leicester and Salford. Scarlet fever was proportionally most fatal in Sunderland and Bradford. Two deaths from diphtheria were returned in Plymouth, in Manchester, and in Salford. Small-pox caused 6 more deaths in London, but not one in any of the nineteen large provincial towns. The number of small-pox patients in the Metropolitan Asylum Hospitals, which had declined steadily from 200 to 143 in the three preceding weeks, further fell to 134 on Saturday last; 20 new cases of small-pox were, however, admitted to these hospitals during the week, against 16 and 15 in the two previous weeks. The Highbury Small-pox Hospital contained 11 patients on Saturday last.

The fatal cases of diarrhoea in the twenty towns, which in the eight preceding weeks had steadily increased from 51 to 712, further rose last week to 807. The annual death-rate from diarrhoea averaged 5·6 per 1000 in the twenty towns; it was equal to 5·0 in London, and to 6·3 in the nineteen large provincial towns. The death-rate from diarrhoea among the twenty towns ranged last week from 2·1 in Wolverhampton, to 10·4 in Leicester and 11·2 in Salford; Salford among these towns has shown the largest proportional fatality of diarrhoea during the past four or five weeks.

The deaths referred to diseases of the respiratory organs in London, which had been 200 and 195 in the two preceding weeks, further declined to 152 last week, but exceeded the corrected average weekly number by 7. Of these 152 deaths 87 were attributed to bronchitis and 47 to pneumonia. The annual death-rate from diseases of this class was equal to 2·2 per 1000 in London; it was 3·4 in Liverpool, and 3·9 in Salford.

HEALTH OF SCOTCH TOWNS.

In eight of the largest Scotch towns, having an estimated population of rather more than a million and a quarter persons, the annual death-rate last week averaged 20·1 per 1000, showing a further slight increase upon the low rates, 18·4 and 19·8, in the two preceding weeks; this rate was, however, 4·7 below the average rate in the twenty large English towns. The rates in the eight Scotch towns ranged from 15·9 and 18·1 in Paisley and Aberdeen, to 23·4 and 24·0 in Perth and Leith. The fatal cases of the seven principal zymotic diseases in the eight towns were 122, against 117 and 125 in the two preceding weeks; they included 51 from diarrhoea, 29 from scarlet fever, 17 from fever, 10 from whooping-cough, 8 from diphtheria, 7 from measles, and not one from small-pox. The annual death-rate from these seven diseases averaged 4·9 per 1000 in the eight towns, against 7·8 in the large English towns. The excess of the zymotic death-rate in the English towns was almost entirely due to the greater fatality of infantile diarrhoea. The zymotic death-rate in the Scotch towns ranged upwards from 1·1 and 2·0 in Paisley and Greenock, to 5·6 and 16·0 in Glasgow and Leith; the excess in the zymotic death-rate in Glasgow was due to fever, scarlet fever, and diarrhoea, while it was caused by scarlet fever and diarrhoea in Leith. The fatal cases of diarrhoea in the eight towns, which had been 39, 59, and 61 in the three previous weeks, declined to 51 last week; the annual death-rate from this disease did not average more than 2·1 per 1000, while in the English towns the rate was equal to 5·7. The highest rates from diarrhoea in the Scotch towns occurred in Dundee and Leith. The 29 deaths from scarlet fever (an increase upon recent weekly numbers) included 13 in Glasgow, 12 in Leith, and 4 in Edinburgh. Six of the fatal cases of measles occurred in Glasgow; and diphtheria caused 4 deaths in Glasgow, and 2 in Greenock. The deaths referred to fever, which had been 13 in each of the two previous weeks, rose to 17 last week, of which 11 were recorded in Glasgow, and 2 both in Dundee and Perth. The deaths attributed to acute diseases of the lungs (bronchitis, pleurisy, and pneumonia) were 70 in the eight Scotch towns last week, against

59 and 67 in the two preceding weeks; the annual death-rate from these diseases was equal to 2·8 per 1000, against 1·9 in London. The causes of 98, or 20 per cent., of the 499 deaths registered in the Scotch towns last week were uncertified; in the English towns the proportion of uncertified causes of death scarcely exceeded 2 per cent.

HEALTH OF DUBLIN.

The rate of mortality again showed a marked excess in Dublin last week, and was equal to 35·3 per 1000, against 28·2 and 35·3 in the two preceding weeks. During the past six weeks of the present quarter the death-rate in the city has averaged 31·8 per 1000, against 22·0 in London and 18·1 in Edinburgh. The 213 deaths in Dublin included 59, or no less than 28 per cent., which were referred to the seven principal zymotic diseases, showing a marked further increase upon the 35 and 43 returned in the two preceding weeks; 4 resulted from small-pox, 5 from measles, 15 from scarlet fever, 7 from whooping-cough, 5 from different forms of fever, and no less than 23 from diarrhoea. The annual death-rate from these seven diseases was equal to 9·8 in Dublin last week, against 7·6 in London and 3·4 in Edinburgh. The 4 fatal cases of small-pox showed a further decline from recent weekly numbers, as did the five deaths from measles. The deaths from scarlet fever, whooping-cough, and diarrhoea, however, each showed an increase. The fatal cases of diarrhoea, which had been but 4, 5, and 9 in the three previous weeks, rose to 23 last week, and were equal to an annual rate of 3·8 per 1000; this rate, although showing a marked increase upon the rates in recent weeks, was considerably below the average rate in the twenty large English towns.

VACCINATION AND SMALL-POX: MR. HOPWOOD'S RETURNS.

On the same evening that Lord Hartington announced the intention of the Government not to persevere with their Act to amend the Compulsory Vaccination Act, the President of the Local Government Board was interrogated by Mr. Hopwood (who in recent years has been the principal mouthpiece of anti-vaccinators in the House of Commons), as to a parliamentary return which was called for by him in June, 1879, but which was not printed till 25th February last. It was objected by Mr. Hopwood that the return in question gave more information than was ordered, and asked the President of the Local Government Board on whose authority this information was added; he also asked whether the added information was not misleading, and whether there would be any objection on the part of the Government to give a return of the numbers of deaths from small-pox in England and Wales during the four years 1843-6. Mr. Dodson replied in effect that the information complained of was inserted in a note to the return on the authority of the late Registrar-General because he was of opinion that the return, without this addition, would mislead the public as to the true relations between compulsory vaccination and small-pox mortality. The truth is that in a previous return, asked for by Mr. Hopwood, anti-vaccinators had obtained certain information, so arranged as to lead to an entire misconception of the true bearing of the facts, and to the founding thereon of entirely false conclusions. The late Registrar-General, therefore, when he found himself again in the position of being called upon to furnish a return which was calculated by its arrangement, and by its only partial statement of facts, to further mislead the public, very properly added on his own responsibility other facts which are necessary to the formation of a sound conclusion on the controversial points at issue. In Mr. Hopwood's second return, to which the Registrar-General made the additional note, a comparison of small-pox mortality is made between the seven years 1847-53, and the nine years 1868-77, the latter period including the fatal epidemic of 1871-2. This partial comparison of selected short periods is obviously intended to minimise the apparent beneficial effect of compulsory vaccination. The Registrar-General shows in his note (so objectionable to anti-vaccinators) that taking the whole period, for which the information is available, both before and after vaccination became compulsory, the average annual rate of mortality from small-pox in England and Wales declined from 420 per million between 1838 and 1853, to 216 per million in the 25 years 1854-78. In another part of the same return, dealing with infant mortality, the mortality from eight causes, supposed by anti-vaccinators to be influenced by vaccination, was asked for. It was this portion of the previous return which had been

most mischievously misunderstood, and had led to the false assertion that infant mortality had increased under the influence of vaccination. The Registrar-General has wisely shown in this return, by the addition of two lines to the table, the death-rate from *other* causes, and from *all* causes, thus effectually disposing of the asserted increase of infant mortality. It is true that the mortality from bronchitis and diarrhoea has considerably increased, but who will believe that this is due to vaccination when it is more than balanced by a decline from other causes. With regard to Mr. Hopwood's wish to have a return of the deaths from small-pox in the four years 1843-6, it is to be hoped that the Registrar-General may be instructed to have the causes of deaths in those years abstracted and classified. It seems a matter for great regret that the series of national mortality statistics for the 42 years of civil registration, from 1838 to 1879, should be broken through want of the statistics for those four years.

MORTALITY STATISTICS OF WATERING-PLACES.

At this season of the year the mortality statistics of watering-places have a special interest, affording as they do an indication of the sanitary condition of these health and holiday resorts. The Registrar-General in his Quarterly Return just published supplies his usual table of mortality statistics relating to forty-six of the principal English and Welsh watering-places and summer resorts. It has frequently been a source of complaint on behalf of the local sanitary authorities, that the Registrar-General's statistics do not relate to the precise sanitary districts over which their jurisdiction extends, but to the registration districts or sub-districts in which they happen to be situated. With reference to this objection and the inclusion within the area taken to represent the watering-place of surrounding rural parishes, the Registrar-General remarks:—"This, though doubtless a matter of interest to the sanitary authorities severally interested with the care of a watering-place and of the district outside its limits, is of comparatively little importance to the holiday-making visitor, who by no means confines himself to the immediate boundaries of the place in which he actually sleeps." If, as is frequently asserted, the sanitary reputation of certain watering-places suffers through the inclusion of surrounding rural parishes, it cannot be without use that the public should be in possession of trustworthy statistics for their immediate surroundings as well as for the watering-places themselves. During the second quarter of this year the general sanitary condition of the forty-six health resorts, judged by their mortality statistics, was eminently satisfactory; the annual death-rate from all causes was only 17·0, and the zymotic death-rate was but 1·5 per 1000. The death-rates of Herne Bay, Littlehampton, Lowestoft, and Dover were exceptionally low, being under 12 per 1000; whereas the ratio was considerably above the average in Hastings, Beaumaris, Bangor, Llandudno, Rhyl, Southport, and Blackpool. Of the zymotic death-rate in these watering-places, the Registrar-General gives full details in his table. It appears that during the three months ending June last the zymotic death-rate (which, as we have said, averaged only 1·5 in the forty-six watering-places) was equal to 3·9 in Hastings and St. Leonards, 3·8 in Dartmouth, 4·2 in Rhyl, and 4·3 in Blackpool. This high zymotic death-rate was mainly due to measles in Hastings, and to scarlet and enteric fever in Blackpool. How far these rates would be modified if the statistics related to the several precise urban sanitary districts it is impossible to say. It is more than probable, however, that in most of these cases the Registrar-General's rates somewhat understate the true rate of mortality. In Blackpool, for instance, which includes a considerable area outside the borough of that name, it is reported that the 9 deaths from scarlet fever and the 7 from enteric fever were all recorded within the borough and urban sanitary district. The prosperity of a health resort is so entirely dependent upon its sanitary reputation that the local authorities and the ratepayers cannot afford to ignore the true bearing of such statistics as those just published by the Registrar-General.

HEALTH MATTERS GENERALLY AT HOME AND ABROAD.

THE HEALTH OF THE CUSTOMS' OFFICERS.

Dr. Walter Dickson's report on the health of the out-door officers, watermen, messengers, &c., of her Majesty's Customs, in the Port of London, during the year 1879, is, as

usual, of much interest from the example it affords of the incidence of sickness and mortality among a selected body of men living, for the most part, amidst the general population of London. The number of officers to which the report applies was 933, extra-officers who form a considerable portion of the establishment staff not being included. The mean daily number incapacitated by disease or accident was 37, or 4.0 per cent. of the strength. The ratio of admissions to the sick list was 72.0 per cent. of the mean strength of the force, and the mean duration of each case was twenty days. The deaths were 13 in number, or at the rate of 13.5 per 1000, and the superannuations 2 in number, or at the rate of 2 per 1000. The death-rate did not exceed the annual averages, and the superannuation rate was much below the mean of many years, which is 7 per 1000.

The force is divided into two principal bodies, one stationed at Gravesend, the other within the metropolitan limits of the port. The duties differ in the two sections, and the Gravesend section is formed of younger men, who are chiefly engaged in boarding vessels, and who live on shipboard. There are differences in the incidence of disease in the two sections, but not more than would be anticipated having regard to the difference in ages. As a rule the maladies attacking the Gravesend section are transient in character, while those attacking the metropolitan section are of a more chronic nature.

The year 1879 was remarkable for an almost unprecedented deficiency of temperature, of solar light, and for an excessive rainfall. This exceptional meteorology very markedly influenced the occurrence of disease among the men. Affections of the respiratory organs and tracts preponderated; next in order of frequency came rheumatic gout, and then, as third in place, nervous diseases. With respect to gout and nervous diseases, Dr. Dickson observes, "Gout was remarkably prevalent in the London force, one-fourth of the whole number of admissions on the sick list, or 19 cases, being due to that disease, which, common as it is among Customs' officers, has never before been observed to occur in such large proportion. Most of those affected had a constitutional or inherited tendency to the malady, but is developed in a very remarkable manner in such persons by certain atmospheric conditions, of which humidity and sudden rise of temperature appear to be the chief. On some days with weather of this kind it was not unusual to find two or three fresh cases of well-marked gout. At this season (spring) neuralgia, vertigo, and other nervous disorders were also in excess, but chest affections were in less than the usual proportion. The brief period which might be termed summer was notable for the extreme fewness of cases of disordered stomach and bowels, only six cases of diarrhoea having been placed on the sick list of the London force during the third quarter.

By a wider distribution of the residence of the officers in the suburbs and along the course of the river, as the dock accommodation down stream is extending, it is very obvious that Dr. Dickson's duties are becoming much more onerous; and it does not appear that the Board of Customs has made any provision to facilitate the execution of Dr. Dickson's functions, or in any other way to meet difficulties which must now be experienced in giving medical attention to the river force, by the altered circumstances of its distribution.

FEVER IN IRELAND.—DR. SIGERSON'S FINAL REPORT.

Dr. Sigerson has presented to the Mansion House Relief Committee a final report "On Destitution-Diseases in the West." This report brings out in a very clear light the relation between the prevalence of fevers in the distressed districts and the distress, and again raises the question whether there was not some lack of foresight on the part of the Irish Administration in meeting and dealing with the calamity. Of course Dr. Sigerson writes after the fact, but when we learn from him the extraordinary falling off in the yield of the potato crop year by year since 1876, together with agricultural losses from other sources, and ascertain how sensitively the death-rates appeared to have been affected by these losses, we cannot avoid the conclusion, having regard to previous terrible experiences of Ireland in this matter, that the distress of last winter and the present year, and the numerous evils arising from it, should have been anticipated and provision against them have been made accordingly. The problem, difficult though it may be, is certainly more simple than that of the famine in India, yet it does not seem to have been approached in the comprehensive manner in

which the Indian problem is being attacked. The report forms an important contribution to the history of the still unended distress, and ought to prove of the highest value in indicating the extreme importance of forecasting and warding off future periods of distress. With all due deference to the Principal Secretary for Ireland as to there having been much exaggeration of the distress in some cases, we are still of opinion that even now we have not an adequate knowledge of the present and past condition of things in the distressed districts. There is a world of pathos, and much room for painful reflection, in Dr. Sigerson's observation:—"The exceptional high death-rate (of the distressed districts) demonstrates that many must have quietly succumbed to their sufferings, and silently died out." Dr. Kenny, who was associated with Dr. Sigerson in his work in the west, concurs in the report.

PUBLIC MEDICINE IN FRANCE.

It is interesting to mark the great attention which is now being given to the consideration of the better organisation of public medicine in France, both in Parliament and in the medical press. One of the most important contributions to the subject is a memoir by M. A. J. Martin, recently submitted to the Society of Public Medicine, and which will be found in the pages both of the *Annales d'Hygiène Publique* and the *Revue d'Hygiène*. According to Dr. Martin, while the existing organisation of public medicine in France in view of consultative matters could not well be improved upon, this organisation in respect to administrative matters is singularly ineffective. There is need both in the educational and in the administrative aspects of the subject for arrangements, financial and other, which would give coherency to the existing organisation and admit of the establishment of a complete system of public health administration, consultative and administrative, throughout the country. Evidently very much has to be done in this direction in France, but the impression left on our mind by M. Martin's paper is that in the desire to indicate the requirements of a perfect system he has not given due regard to the practical difficulties that lie in the way. We were scarcely prepared to hear that the defects in the system of public medicine in France are so grave in their practical aspects as now it appears they are—that the system is, in fact, largely a "paper plausibility;" and we fear that there is a danger in the movement for reform now in progress of substituting theoretical conceptions of what is desirable for measures strictly adapted to the wants and capabilities of the nation and of its different communities.

FAMINE IN ASIA MINOR.

Recent news from the famine-stricken districts in Asia Minor give a deplorable account of the state of the populations in the districts between Erzeroum and Bayazid, and in the districts of Van and of Mossul and the intermediate tract of country. The scarcity of food in these localities is extreme, and in many places the people have been trying to support life on wild herbs. The deficiency and high price of grain has, moreover, led to not more than a fourth of the usual amount being sown. The destruction among the flocks in the affected districts, partly from the severity of last winter and partly from the want of forage, has been enormous. It is estimated that half the oxen and three-fourths of the sheep have perished. Deaths from starvation have been very numerous, and the evidences of chronic starvation among the survivors are shockingly apparent. Typhoid, typhus, dysentery, scurvy, cerebro-spinal meningitis, and small-pox are mentioned as the most prevalent diseases in these districts, and fears are entertained of some localities that, unless the Ottoman Government interfere with relief, worse evils from want than have yet been experienced are still in store.

A project for the creation of a Faculty of Medicine in the University of Odessa has been submitted to the Imperial Minister of Finance. The annual cost of the Faculty is estimated at 127,000 roubles, and the construction of buildings at 600,000 roubles, of which the municipality undertake to subscribe one-fourth.

A conference of the medical profession in Catherinoslaw was held on July 22nd to consider measures for arresting the spread of diphtheria and small-pox, both of which diseases were then very prevalent in the government of that name.

The *Indian Medical Gazette* states, on the official authority of the *Calcutta Gazette*, that the "Burdwan fever" may now be considered a matter of history. How terrible the devastation of this disease must have been during its prevalence may be inferred from the fact, given on the authority of Dr. Coates, that in the villages situated along dried-up watercourses in the districts which had been affected by the fever, scarcely one-tenth of the people were left alive. Dr. Coates believes that the fever was caused by the organic filth which the soil-water gained from the soil, rather than by the soaking of the soil *per se*.

The new drainage system adopted by the Slough Sanitary Authority has been completed, and was formally opened a few days ago. The pumping station and tanks are situated near Chalney, a village to the north-west of Eton College. The sewage is conveyed from Slough by a capacious conduit about a mile in length to the pumping station, whence it is forwarded to a farm at Dorney, and utilised by a process of irrigation.

The fort of Vincennes, near Paris, has been temporarily evacuated in consequence of the outbreak of typhoid fever amongst the garrison. In a few days 120 soldiers are said to have been attacked by the disease, though in a mild form.

It would appear that legislation is likely to take place giving the much-needed power to the Calcutta Port Commissioners to regulate the hours during which European sailors in the port may be required to work in the sun.

MEETING OF THE BRITISH MEDICAL ASSOCIATION AT CAMBRIDGE.

THE annual dinner of the Association was held on Thursday, August 12th, in the hall of Trinity College, covers being laid for 350. The speeches to the numerous toasts were long, and it was a late hour before the company dispersed. There was some misunderstanding in connexion with the prohibition of smoking in hall, some of the guests not being aware that to smoke in hall is an almost unheard of offence. On Friday morning Dr. Michael Foster delivered his address in physiology to a large and appreciative audience in the Senate House. A vote of thanks to Dr. Foster was carried with great cordiality. The work of the sections began at 11, and the business of the meeting was concluded at a general meeting at 1:30, when the reports of the Habitual Drunkards, Parliamentary Bills, and Out-patient Reform Committees were received and adopted. At 4 o'clock the President and Mrs. Humphry gave a garden party at the Fellows garden of King's College, and at 9 P.M. the master of St. John's College received the Association and other visitors in the Combination room of the College. The extensive grounds of the College, the Bridge of Sighs, and the river were beautifully illuminated with Chinese lanterns, and there was but one opinion expressed of the brilliant success of this conversation. Saturday was devoted by those who stayed to excursions to various places of interest in the immediate vicinity. Thus ended a meeting which, though not marked by any scientific work of very unusual moment, was thoroughly enjoyed by all present.

Surgery Section.

At the conclusion of the debate of "Lithotripsy at one Sitting," Mr. Lund (Manchester) read the notes of a case of Sarcoma of the Shoulder, for which he performed amputation of the upper limb, scapula, and one-third of the clavicle. The patient recovered, and was exhibited, the result being excellent. Mr. Edmund Owen then read a paper in which he urged that since the introduction of anæsthetics it was wrong to use the hot bath for strangulated hernia, because its good effects could be much more surely obtained from anæsthesia, and the time spent in the bath and the subsequent manipulation were often injurious. The sooner and with the less manipulation a strangulated hernia was reduced the better. Mr. J. Wood maintained that heat was really bad, for it caused the expansion of the

gas in the intestine, and increased the tension in the sac. He, therefore, preferred the use of an ice-bag, and if after it the taxis failed he at once put the patient under the influence of ether, and operated. Mr. Keetley thought heat was useful. Mr. Herbert Page then read a paper on the Immediate Suture of Divided Nerves. After alluding to the experience on the subject already accumulated, he detailed two cases lately in St. Mary's Hospital in which the median nerve was divided in the arm. Immediate suture of the nerve was followed in each case by a very considerable restoration of both sensory and motor function, in one case almost complete. Both the cases were treated antiseptically. At the close of the meeting, Dr. Warren of Boston exhibited a variety of trocars, probes, sounds, bougies, catheters, and evacuating catheters made with a spiral point, which, combining the advantages of the wedge and the inclined plane, were stated to be introduced with greater ease than those generally in use.

On Friday morning the chair was taken by Mr. J. Wood, in the absence of Mr. W. S. Savory. The first business was a debate on the Treatment of Stricture of the Urethra, introduced by Sir H. THOMPSON, who gave a brief and lucid review of the modifications introduced during his own personal experience—the last thirty years. Starting from the time when Syme in Edinburgh was warmly contending for the superiority of external urethrotomy over the employment of caustics, then warmly advocated in Paris, London, and elsewhere, he noted the introduction of soft instruments, which have to a large extent replaced the metal ones, and adverted to the operations of splitting, over-distension, and internal urethrotomy. On looking back over this period, it was satisfactory to be able to see that decided progress had been made. To assist discussion, he formulated the improvements in treatment in five propositions: 1. There is now a general recognition of the principle that a delicate manipulation of the urethra is alone permissible. The rough handling so commonly seen years ago is now universally condemned. 2. The old rigid metallic instruments so often used with danger, if not actual damage, have been superseded wherever possible by elastic, pliable, soft, and taper instruments, which are far safer. 3. There is now a more general recognition of the fact that there are very few strictures indeed which cannot be traversed by an instrument, if only the surgeon gives time, patience, and dexterity. 4. It is now generally accepted that the dilatation of strictures can be carried with safety and advantage to a higher degree than was formerly considered admissible. 5. Internal urethrotomy has been substituted for rupture, caustics and external urethrotomy in nearly all cases requiring an operation. "When a surgeon fails altogether to pass an instrument, perineal section still proves to be a valuable operation. It is curious to note how the various measurements of the urethra given by different surgeons and anatomists have varied; in truth the urethra is not such that it can be exactly expressed, for it has no definite size or calibre when not in use for the passage of urine or a foreign body. It is a very dilatable canal, and the natural dilatability of it varies with the condition of the external surrounding structures. Pearson used bougies of No. 20 English scale, so that the use of large instruments is not a modern invention; but it is probable that surgeons have erred of late in not availing themselves of the great dilatability of the urethra. I must, however, caution you that my experience has amply convinced me that it is easy to damage the canal irreparably by over-distending it. I must also oppose the doctrine now sometimes held, that stricture is curable by complete section of it; I have seen too many cases where the most thorough and complete division of all the stricture tissue has been followed by a relapse to dogmatise on this point; indeed there are very few cases of perineal section which are not followed by recurrence. But the recurrence is very rapid if the stricture is not thoroughly divided. In my hands internal urethrotomy has been as safe and as efficient as Syme's operation. Splitting and over-distension are not so efficient as a well-performed urethrotomy, for a complete division of the stricture tissue is the required object; and I may observe that many of the proposed modes of performing this operation cannot accomplish this. The principles to be borne in mind in undertaking internal urethrotomy are: 1. The necessity of a careful physical examination before the operation, to detect the precise position, size, and nature of the stricture and the condition of the whole urethra. The instruments I always employ for this purpose are metal bulbs on slender stems. 2. The

necessity of completely dividing all the stricture tissue, which is generally most efficiently done by a slender cutting blade introduced through the stricture concealed, and then protruded and drawn outwards. 3. A full-sized catheter should be retained in the bladder for some hours after the operation. 4. Full-sized bougies should then be passed at occasional intervals, to prevent union of the incision by first intention. I, of course, prefer my own instrument, and although very few strictures requiring incision will admit any instrument of the size of No. 5 when they first come under treatment, I have never seen one which could not be brought up to that size by tying in a smaller instrument for a few days. The method of cutting from before back may, however, be safer in untrained hands. The operation has very slight risk attached to it, and I have found that the patients are very comfortable for the first three to four years, but after that they are often compelled to lessen the size of their bougie one or two numbers, but have no symptoms, and then from seven to twelve years after the operation symptoms usually reappear; and I have often recommended a repetition of the operation, in one case I have done it three times. The great desideratum at the present time is a mode of treatment which shall restore the natural dilatability of the urethra; but I believe that no one who has carefully studied the pathology of the affection can hold that any of our present methods will accomplish this end.

Professor MACLEOD.—A careful attention to the kind, extent, and position of a stricture must guide us in our choice of its treatment. A traumatic stricture differs altogether from others, for in it there has been usually a transverse rent in the urethra, which results in a contractile cicatrix; while in a stricture the result of inflammation the mucous membrane is not involved, and there Holt's operation is beneficial, while it only renews the rent in the traumatic form. There is much importance also to be attached to the preparation of the patient for operation—rest for some days, diet, temperance, abstinence from tobacco, regular action of the bowels, healthy urine, and the administration of quinine both before and during surgical treatment have been of use to me, so also opium. It is important also to know precisely the state of the bladder and kidneys before operation, and as an adjunct to gentleness of manipulation I would urge the use of anæsthetics whenever we employ instruments. In my opinion cure can never be obtained. I would divide strictures into—(1) recent limited; (2) old circumscribed; (3) old, extensive, and undilatable; (4) resilient; (5) traumatic. For No. 1 I use Holt's operation, and have never seen any bad results or trouble from it, but I do not think of passing instruments at once after it, and usually wait four days. For No. 2 no treatment is so good as internal urethrotomy by Trélat's instrument, followed up by gradual dilatation. External incision is most valuable for No. 3. If Syme's guide cannot be passed, Wheelhouse's operation is good; the danger of external urethrotomy has been enormously exaggerated. For No. 4 I use both internal and external section. For No. 5, if limited, I cut and then dilate, but if extensive I do a perineal section. Irritability of the canal points to the necessity for constitutional treatment, and if it cannot be cured I should cut the stricture, of whatever nature it be. Multiple strictures are best dealt with one after another. In twenty-five years of hospital practice I have never had occasion to tap the bladder through the rectum, but if hot baths, opium, ice in the rectum, and careful catheterism fail to relieve, I aspirate above the pubes.

Mr. FURNEAUX JORDAN bore testimony to the great value of soft elastic instruments, and added that he had often found that a tiny elastic thread worn in a stricture for a few hours or a day or two occasionally was quite sufficient to keep a stricture in order and the patient comfortable. The same plan was also applicable to rectal and œsophageal stricture. He had relinquished Holt's and Syme's operation for internal incision, for which he used Durham's instrument, which made shallow cuts in four directions, and so must cut the cicatrix. He had treated several obstinate cases by opening the membranous urethra from the rectum, and passing an instrument from behind. He had never had a fistula result.

Mr. REGINALD HARRISON said there were many varieties of stricture, which required different modes of treatment, and the great desideratum was their exact application. He hoped some method of preventing the contractility of scar-tissue might be introduced.

Mr. TEEVAN only differed in a few points of detail from

the conclusions of Sir H. Thompson. When an operation is required certainly internal urethrotomy is the best. If all the deaths due to Holt's operation had been carefully published, that operation would have died a natural death long ago. He had never had a death from internal urethrotomy, and had never heard of one in a young man. No penile stricture ought to be ruptured. No stricture in the bulb should be operated on until milder treatment had been tried and failed, and he would add that no stricture in the bulb should be cut until all narrowings in front had been fully dilated or cut. In his opinion, the struggle had narrowed itself down to rupture *v.* internal urethrotomy. Cases after rupture are traumatic and very intractable, for the rent is not only in the middle line.

Mr. J. WOOD thought rupture a dangerous procedure; he had seen several fatal cases. Internal urethrotomy is the operation of the future; he preferred to do it with an instrument he had invented, by which he can feel exactly the stricture tissue, and cut it only.

Mr. CLEMENT LUCAS was sure that a great majority of cases could be treated by gradual dilatation, and only when this fails should internal urethrotomy be resorted to; the incision necessarily divided more than the stricture. Some cases are curable by gradual dilatation; he lately saw one so treated by Mr. Cock fifteen years ago, who had not an instrument passed for eight years, and yet No. 10 was passed with ease. He referred to the operation commonly known as Cock's perineal section, and described it.

Mr. MACCORMAC remarked that Mr. Simon had performed and described that operation before Mr. Cock did it. He lately performed internal urethrotomy on a "bleeder," who very narrowly escaped death.

Sir H. THOMPSON replied that any operation of merely nicking the urethra was not an internal urethrotomy, which must be made quite through the stricture. There is no danger in a simple longitudinal incision in the urethra; it heals by first intention without any narrowing. He generally made a cut from two to four inches long. He was very glad to hear from so many speakers such unanimity as to the value of internal urethrotomy.

Several papers were then read, and the section adjourned.

Pathology Section.

Continuing his summary of the errors which are liable to arise in the study of the part played by the nervous system in causing derangements of nutrition, Mr. Hutchinson next referred to the fallacies arising from a failure to recognise simple local causes of such derangements. In the case of furring of the tongue on one side, which has been attributed to irritation of the fifth nerve, he had reason to believe that it was always due to the patient not eating on that side of the tongue. Again, we must remember that diseases of the nervous system have a marked effect in causing a derangement of the entire nutritive secretion of the body, that the nutrient fluids are thereby deteriorated, and there is a tendency to atrophy of the tissues, especially such as bones. In paralysed parts another factor tending to degradation of structures comes into play—namely, the enforced rest of the part. With regard to the distribution of nerves, there were also several important points. Especially important was the inquiry whether a part is well supplied as to sensation. Even unsuspected local defects in sensation might yet act on the vaso-motor system, the local distribution of blood, even in inflammation being largely dependent on reflex sensory excitation. In connexion with this it might be observed that neuritis was probably of very frequent occurrence, though difficult to recognise, for it is often seen in the eye without any general affection of health and with no obvious causes, and might disappear without leaving any marked results. Insidious neuritis might thus involve any nerve. Again, it does not follow because a disease is along the tract of a peripheral nerve that it is due to nerve lesion. Such is the complexity of the peripheral nervous system, that it might well be that it was only the peripheral termination organs, such as the Pacinian bodies, which were diseased primarily. So in the case of joints, he thought it probable that they might become anæsthetic in consequence of degeneration in the peripheral nervous system, and the power of sensation being thus lowered, they were more liable to local irritations. Thus partial diminution of the power of sensory nerves supplying a joint, apart from central disease, might cause joint degeneration. Turning now to the general question, Mr. Hutchinson stated the different views as to the trophic

action of nerves, dividing them roughly into the view that all the action was vaso-motor, or that there was in addition a special trophic influence. Before accepting the latter view, all other hypotheses should be exhausted. And certain facts must also be considered as militating against the trophic hypothesis, which might be summed up in these—the great rarity of some of these affections which on the trophic hypothesis should be common; the peculiar characters which they present; the remarkable differences observed in these lesions, which are supposed to be dependent on a common cause, and their great resemblance to others which are not of neurotic origin. Mr. Hutchinson then gave a list of the conditions which are supposed to be dependent on trophic nervous derangement:—Bedsores in cases of paralysis; ulceration of the cornea in injury to the fifth nerve; sympathetic ophthalmitis; herpes zoster; glossy skin in cases of partial section of nerves; arthritis following diseases of the spinal cord; *digitus mortui*; morphea; osteo-malacia; the condition of the skin and bones in leprosy. He then proceeded to inquire in detail whether amongst these there was any one in which no other explanation could be given than that they depended on trophic nerves. The first group, which he called the “anæsthesia group,” comprised bedsores and ulceration of the cornea. As to bedsores, he still believed, in spite of Charcot’s observations, that they were really pressure sores, due to pressure or friction on parts deprived of sensation; and in proof of this he cited the clinical fact that if there is motor paralysis on one side and sensory on the other, the bedsores occur only on the side where there is sensory paralysis. The position of the patient also aided in the production of the pressure. He thought that the fact that continuous pressure very speedily causes local gangrene in a healthy part was not sufficiently recognised by physicians. When once inflammation was started in a part deprived of sensory nerves, the inflammatory process was liable to be peculiar, owing to deranged reflex stimulus. With regard to ulcerated cornea in paralysis of the fifth nerve, he believed it never suffered until a local cause was applied, such as heat, dust, or the like; and when set up, the kind of ulceration was precisely analogous to that occurring in persons in a low state of health. *Reflex or sympathetic ophthalmia* was formerly regarded as a conclusive case of reflex nervous action; especially where, as in some cases, the disease was similar in the two eyes. But he must cite a competitive hypothesis—namely, that instead of being induced through the nervous system by reflex action, the disease might actually travel along the nerves themselves, the nerves merely playing a passive part. In proof of this he mentioned that an interval of three to five weeks is always needed after the injury before the other eye becomes affected, and even if the injured eye is extirpated after an interval of a week, inflammation may yet occur in the second eye. This fact would indicate the slow passage of some pathological change of a nutritional rather than a reflex character. *Neurotic iritis* of spontaneous origin was another illustration of the same kind. *Herpes zoster*, a disease usually regarded as due to nerve lesion, had the peculiarities distinguishing it from other herpes, of certain limitation over sensory nerve terminations, that it is preceded by pain, always leaves scars, tends to cure, and rarely recurs; never, in fact, in the same nerve. His theory was that it is due to neuritis of a sensory nerve, which travels downwards through the trunk of the nerve, and attacks the terminal filaments at its extremities. The next is the *catarrhal group*, including nasal catarrh and rheumatism. Nasal catarrh he believed to be usually reflex from a chill on some part of the chest or respiratory tract, causing an exaggeration of the ordinary function, due to reflex dilatation of vessels. Rheumatism might probably be analogous, the reflex action affecting the joints instead of the nasal mucous membrane. Age and idiosyncrasy were here seen in action in modifying the effects, both catarrh and rheumatism tending to become chronic in the aged. Mr. Hutchinson next referred to a group of cases in which the distribution of nerves leads to the supposition that they are due to nervous influence. Hemiatrophy of the face or scleriosis cutis, the keloid of Addison, seemed to belong necessarily to the fifth nerve, as also morphea, which was usually unilateral; but he was inclined to think that, though located by sensory nerves, they depended on disease of the vaso-motor filaments which travel with the nerve—these being seats of permanent disease—and not on the fifth itself. As an illustration of a similar condition, he showed a skull and lower jaw which was the seat of unilateral hyperostosis and

exostosis, probably due to a similar condition—namely, a vaso-motor derangement distributed by the fifth nerve. Mr. Hutchinson summed up his able address by a classification of the conditions liable to give rise to error, and expressed his general disbelief in the direct trophic influence of the nervous system. A large number of diagrams and specimens were used to illustrate the various points under consideration.

The discussion was commenced by Dr. BROWN SÉQUARD, who expressed his dissent on many points from Mr. Hutchinson. He narrated experiments on dogs which proved conclusively, in his opinion, that bedsores could be produced at will by inflammation in the cord, apart from any external irritation, and with the most extreme care. Moreover, they could be prevented and cured by the alternate application of heat and cold. He believed that the nervous system had five or six different methods of action on nutrition apart from the vaso-motor system. Amongst them the power of attracting blood to the tissues, and producing increased nutritive action, was very important. He cited his recent experiments on collapse to show the nerve influence on the tissues (see THE LANCET, August 14th, p. 268-9).—Dr. BUZZARD reverted to the subject of unilateral furring of the tongue, and mentioned a case where it was associated with neuralgia of the fifth nerve and increased flow of saliva on the same side. He mentioned, also, cases of brittleness of the bones and spontaneous fracture associated with symptoms of *tabes dorsalis*. He cited also the fact that disease of the spinal cord had recently been discovered both in lead palsy and in leprosy, and mentioned a case of recurrent herpes associated with *tabes dorsalis*. With regard to bedsores, he entirely differed from Mr. Hutchinson, and pointed out that they occurred only in a special class of cases.—Dr. CLIFFORD ALLBUTT also mentioned cases opposed to Mr. Hutchinson’s views as to the cause of bedsores, furred tongue, and herpes zoster.—Dr. WILKS suggested that the subject must be discussed as a matter of clinical observation. He thought the relations of some diseases, such as erysipelas, pleurisy, and herpes zoster, to reflex irritation had not been sufficiently considered.—Dr. DICKINSON considered the effects of mental influence on nutrition.—Mr. HUTCHINSON, in reply, maintained the views he had expressed, but allowed that he had stated the facts somewhat dogmatically and with little qualification, desiring to arouse discussion.

Dr. BUZZARD then read a paper on some Cases of Joint Affection in Locomotor Ataxy, associated with Gastric Crises, which he illustrated by admirable photographs. He suggested that co-existence and apparent relation of the gastric symptoms with the joint disease might be explained by the existence of a trophic centre for the osseous and articular system in the vicinity of the vagus roots in the medulla oblongata. This hypothesis would, if confirmed, help to explain the co-existence of cardiac and arthritic affections in acute rheumatism and the occurrence of hyperpyrexia.—No time remaining for the discussion of the paper, Sir James Paget, as President, closed the meeting with the felicitous remark that it was well to end in doubt.

At the meeting of the Section on Thursday, Aug. 12th, the hall was crowded from floor to ceiling with an audience eager to hear the address of the President, Sir JAMES PAGET, on “Elemental Pathology.” This had been postponed until the second day on account of the numerous claims on the attention of the members on the previous day. It proved to be a wise step, for the other Sections were completely emptied, and obliged to suspend work until the conclusion of Sir Jas. Paget’s address.

Commencing with the observation that the complexity both of structure and of surrounding conditions of the human or animal body rendered the study of pathological problems a difficult and complicated one, he suggested that these might be worked out to some extent in plants and minerals. This study, which he would call “Elemental Pathology,” could be carried on at leisure moments. He had found a very large number of papers on diseases and injuries of plants since he had given attention to the subject. First of all, he would direct their attention to the hypertrophies and atrophies of plants. Hypertrophies were important because in plants they were not related to function, but simply to supply of nutritive material; thus the “ringing” of trees causes an hypertrophy analogous to that produced in the human body by the obstructed return of lymph. Again, suppression of one organ led to hypertrophy of another, the adiposity resulting from castration of an animal having its parallel in the artificial hypertrophy of fruits—in both cases, perhaps,

some nutriment being in excess. Atrophies are rare in plants, but degenerations common. Thus senile degenerations are well illustrated by the changes which take place in leaves preceding their fall. The degenerations found in the "sere and yellow leaf" throw light on symmetrical disease; for when a leaf is of symmetrical form, such as palmate, or equal ovate, the decay is commonly symmetrical. In the human body the presence of a circulation and a nervous system were puzzling, and the theories of symmetrical disease attributed symmetry either to a general change in the blood or to the action of nerve terminations disposed in a like manner, but here it was seen that neither blood nor nerve disease was requisite to cause symmetrical decay. Again, the mode of decay and fall of leaves show that decay is not death, for, as Sir James Paget pointed out, dead leaves do not fall, the necessary antecedent changes are vital processes. He then described in some detail the processes which occur in the leaf, stem, and stalk preparatory to the fall of leaves, a process first worked out by Dr. Inman, of Liverpool. These changes, consisting in a gradual change by division of cells and their conversion into cork tissue takes place both in the leaf and the stem, by concurrent actions which are, however, not concatenate, though they proceed in the same measure, time, and place, like two bees working together, thus showing that such changes were not necessarily due to any central controlling activity. When, by the formation of two parallel layers of primordial cells and their division the leaf is now ready to fall, it hangs only by a delicate central thread, which is the so-called fibro-vascular bundle, a special structure made up, not of ordinary parenchymatous cells, though developed from them, but of more highly organised parts, fibres and vessels, to carry sap. This might be compared to a vertebrate column, it has so low a vital power that it cannot degenerate, though we consider it more highly developed. So, too, is it not the case that many of the changes which we call higher developments are from the point of view of vitality degenerations. Bone, for example, is allied to calcareous degeneration, and though it has acquired higher uses, it has also attained lower vital properties. In seeking a parallel in the vegetable kingdom for a rickety child, none seemed to him so suitable as the green roses, devoid of proper colour and odour, which florists had succeeded in producing. Passing next to the repair of injuries in plant structures, he observed that it was much less perfect than in animals; the reparative process very rarely proceeding beyond the mere protection of the injured part, scarcely ever any reproduction of parts being observed. The only exception he knew was one moss, which could partially reproduce a leaf, but not the midrib. When plants were injured by wounds, layers of cork cells are formed around, which may grow over the wound, or a gummy exudation is poured out, but the epithelium never reforms. So wounds of branches never heal, the sole exception being when the wound only reaches the cambium. Continuing this subject, the speaker drew a striking contrast between the stumps of trees and of amputated limbs, remarking on the fact that wounds of trees are a prey to parasites, which do great harm, and suggesting the results of the treatment of such tree-stumps by the methods of Lister and Humphry respectively. Trees showed, too, the "inevitable process of repair" going on in one known case for one hundred and fifty years in a pine tree without complete cure. This law, that an injury which might occur at any age, and have no parallel antecedent in any ancestor, being indeed unique, should inevitably tend to become repaired in a particular way, indicated that there were other laws and properties at work in the body than those accounted for by heredity or evolution. The law was true for crystals as for plants and animals, and seemed to be the general expression of the Divine Will, though not limited by benevolence in particular instances. Two other topics were then in turn discussed, inflammation and specific diseases. Irritants cause inflammation in plants as well as in animals. Specific inflammation was especially well illustrated by galls, which are specific inflammatory hyperplasiae, of which numerous other examples might be found. No less than two thousand kinds of galls were known, all of which are the product of some poison introduced by insects either with the ova or from the mouth in biting, and are all wrought in order to find residence and food for the insects producing them, the disease being in some cases a complex structure adjusted for their sustenance and maintenance. Nor is this all, but

the form of this disease is as characteristic as the insect producing it, so that each can be recognised and attributed to its proper species. Each is a truly specific inflammation, and there are an enormous number of such specific inflammations, their study being thus of the highest interest and importance to the human pathologist. Sir James Paget concluded his eloquent address by urging upon his hearers to study some definite science, apart from their professional studies and work. The bustle and turmoil of daily professional life were unsuited to the proper scientific study of pathology. The astronomer studies astronomy in dark, stormy nights and in the railway train, but his best studies are in the quiet of the observatory and with a calm clear sky. Our life work lies in stormy nights and railway trains; if we desire to study calmly and to profit we must choose some subject which we can carry on apart from our professional work, during our leisure and holidays, which will yet afford lessons of surpassing value. Such a study is that of the diseases of plants.

The address, which occupied nearly an hour in delivery, was characterised by all the ease and clearness of diction, masterly force of language, and felicity of illustration which distinguish the speaker; and the audience showed no sign of any desire to break the spell which bound them in eager attention to the close, or to go back to the work of their own Sections. At its close Professor Humphry moved a vote of thanks to Sir J. Paget for his address, which was seconded by Professor Gross of Philadelphia. An amusing incident occurred during the address; for Professor Humphry, mistaking a pause by the speaker for a cessation, rose to move the vote of thanks, and, turning round to face the audience, did not see that Sir Jas. Paget remained standing and waiting to proceed, until one of the secretaries succeeded in attracting Professor Humphry's attention, when he sat down amidst great applause.

Mr. LISTER then gave an able summary of the investigations of Koch on Septicæmia and Gangrene, of the discovery of the nature of so-called "fowl cholera" by M. Toussaint, and of Pasteur's investigations into its inoculation. He then mentioned the recent experiments with regard to the inoculation of splenic fever or charbon by M. Toussaint in France, and Dr. Greenfield in this country, describing the methods employed. The recent observations by Buchner in reference to the transformation of the hay bacillus into the anthrax bacillus were then mentioned. Mr. Lister showed some specimens from fowl cholera sent by M. Pasteur. — M. TOUSSAINT, who spoke in French, made some observations in reference to the hearty welcome he received, but did not make any statement, Mr. Lister having already described his researches. — Dr. W. ROBERTS referred to the general bearings of the question, and pointed out that bacteria and fungi were beneficial to man in some of their actions, especially the preparation of food, and the causing decomposition. — Dr. LAUCHLEN AITKEN read a brief digest of the experimental results of Klebs and Tommasi Crudeli on the Bacillus Malarie. — Dr. BELL of Bradford gave an account of some cases of Woolsorters' Disease. — Mr. MALCOLM MORRIS described some observations on the Cultivation of Parasitic Organisms in relation to Skin Diseases. — Dr. BRAIDWOOD also mentioned some of his observations in reference to scarlet fever and septicæmia. — Dr. GREENFIELD, who was called upon by the President to make some remarks, observed that the subject as it had been presented was hardly in a state ripe for discussion, and needed much special work before any certain general conclusions could be attained. — Upon the whole the discussion could hardly be pronounced a success, for no propositions were laid down for discussion; and interesting as were some of the facts narrated, their general bearing was not sufficiently clearly stated to attract the attention of those not familiar with the subject; and there was a great lack of obvious connexion between some of the papers and speeches and the matter in hand. The absence of Professor Klebs and Dr. Vandyke Carter, both of whom had been expected to take part in the discussion, and of several others who had sent in their names, contributed to render the discussion much less interesting than might have been expected.

On Friday the Section met—or rather it would appear that the officers of the Section met, for there were scarcely any members present. Papers on Glomerulo-nephritis by Dr. Leech, the Pathology of Psoriasis by Dr. Thin, Congenital Neurotic Papilloma by Dr. Cottle, and Cerebral Embolism by Dr. Dickinson, together with other papers, were read. But it was evident that the interest of the

members of the Association was elsewhere, and the difficulty of forming a quorum led to an early adjournment. On the whole, it would not appear that the annual meeting of the British Medical Association is a favourable field for the prosecution of pathology, or indeed for any serious study. So long as there is eloquence, or prettiness, or great novelty, the attendance is good, but apart from these it immediately languishes. Moreover, it is to be regretted that the various specimens which were illustrative of the communications were not better arranged so that they might be more easy of access and nearer to the room where the papers are read. As it was, a special pilgrimage was required in order to see the specimens to which reference was made in the papers, and the collection was so scattered that it was very difficult to find those of which one was in search. If the Pathological Section is to be continued, this defect should in future be remedied by the collection of the specimens, microscopic and others, either in the room of meeting or closely adjacent to it, and by conspicuous labelling of the specimens shown.

Ophthalmology Section.

On Thursday nearly the whole of the meeting was occupied with a very interesting exposition by Professor Donders of the nature of colour-blindness. The learned professor gave a short *résumé* of our present knowledge of colours, and showed the mode in which he was accustomed to obtain a clear conception of what was really seen by a patient. This consisted in having a circle ruled on a very large sheet of paper, in which were a number of slits. He then prepared a number of slips of paper of different colours, and arranged them like small segments of the spokes of a wheel, radially on the circle, beginning with red and returning to it again through violet. A similar set of slips were given to the patients, and they were told to match them with those placed by the Professor. The method is a most graphic one—the red-colour blind immediately places greenish slips of the colour he conceives red to be immediately below the red ones, and the kind and amount of his colour-blindness can be read off without further trouble, whilst the cards can be kept as a note of the patient. In connexion with this paper others were read, by Mr. Nettleship on "Colour-blindness in Atrophy of the Optic Nerve," and by Mr. Shadford Walker on "Amblyopia and Amaurosis from Tobacco and Alcohol." Dr. Landolt gave a short communication, showing the connexion between malformation of the head and anisometropia. After the meeting broke up, M. Warlomont exhibited a peculiar pair of spring scissors, to which a clamp was fitted in such a manner that when the cut was completed and the scissors removed the clamp remained attached. It seemed that it might be adapted to readjustment operation, and would serve admirably to prevent the tendon from slipping back beyond reach. Dr. Priestley Smith also exhibited a new tenometer, and Dr. Gowers a new form of refraction ophthalmoscope.

The most interesting papers of the last day were those of Mr. Hutchinson on a Recurrent Cyclitis, and an inquiry, in the form of a note, asking for information from those present as to the mode in which they dressed their cases after cataract operations, which elicited the fact that great differences existed, which clearly demand that further inquiries should be made. Two gentlemen closed the eye operated only, all the others closed both. Some applied court plaster only to keep the lids in apposition, but most applied compresses of wool. There appeared to be about an equal number who used them dry with those who used them wet. Some applied leeches early, some only when inflammation had set in. Some did, others did not, employ atropine, and one or two used eserine, especially when the operation was done without iridectomy. A modification of Javal's instrument for the estimation of astigmatism was exhibited. Altogether the meeting of the Ophthalmological Section was most satisfactory. It was ably presided over by Mr. Bowman, and many of the leading ophthalmic surgeons in the country took part in it.

THE following is a copy of the speeches delivered in the Senate House of Cambridge by the Public Orator (Mr. J. E. SANDYS, Fellow and Tutor of St. John's College), on the occasion of the visit of the British Medical Association, August 11th, 1880.

In ipso limine orationis nostrae nihil auspiciatius esse arbitramur quam ut vos, qui consiliorum vestrorum sedem hanc curiam elegistis, totius sanatus nomine omnes salutemus. Qui salutem aliis totiens attulisti, vosmet ipsos omnes salvere iubemus. Athenienses quidem

olim vestro illi Hippocrati auream coronam in theatro publice decreverunt; nos autem, ut nostram erga vos omnes benevolentiam aliquatenus indicemus, et tot viris de humano genere bene meritis, nonnullos, velut exempli gratia, nostra corona qualicunque hodie ornare volumus, qui honos idcirco illis laudi est quod vestra omnium frequentia illustratus, vestro omnium, uti speramus, consensu comprobatur.

Dr. C. E. BROWN-SÉQUARD, F.R.S., *Professor at the Collège de France, Paris*.—Erat nobis in animo Reipublicae Gallicae senatorum illustrem, virum de investigandis humani generis varietatibus optime meritum, nostra laureola hodie decorare. Atqui laurea illa in cypressum mutata est; ille enim, qui ipsum fontem et originem loquendi indicavit, ipse inter omnium dolorem, morte immatura abreptus, conticuit et obmutuit. Quo autem maiore animi aegritudine illum desideramus, eo maiore gaudio eiusdem Reipublicae civem salutamus, qui (ne plura commemorem) ipsam arcem sentiendi in cerebro positam, ipsam carinam illam corporis quae medulla spinalis nuncupatur, fortiter exploravit. Ceterum in tali materia non omnia nobis subtiliter disputanda, non omnia (ut de amicitia Tullius) "ad vivum" rescenda. Vobis igitur praesento Medicinæ Professorem insignem, Edvardum Brown-Séquard.

Dr. F. C. DONDERS, *Professor of Physiology at Utrecht*.—A Rheni Traiecto ad Cami nostri ripas transire dignatus est vir qui pulcherrimo studio dedicatus, disciplinae mathematicae qua nos quoque gloriari sciamus accuratam cum oculorum humanorum exploratione exquisita coniunxit. Laetum profecto est auspicium quod oculis nostris nunc demum contemplari contingit virum societati nostrae Philosophicae honoris causa iamdudum ascriptum, Physiologiae Professorem illustrem, Doctorem Donders.

Dr. S. D. GROSS, of Philadelphia.—Trans fluctus Atlanticos, trans Oceanum non iam ut antea "dissociabilem," patriae nostrae ad portus nuper advectus est vir venerabilis quem inter fratres nostros Transatlanticos scientiae Chirurgicae quasi alterum Nestorem nominare ausim. Ergo libenter quasi fraterno amore hodie salutamus, civitatis bene ominati nominis civem, Chirurgiae Professorem Philadelphensem, Samuelem Gross.

Sir WM. JENNER, Bart., K.C.B., F.R.S.—E fratribus nostris ad nosmet ipsos transimus. Nostris e popularibus unum salutamus, Regiorum medicorum numeromerito ascriptum, qui tum ceteris morbis propulsandis, tum praesertim formidolosae illi febrium cohorti profigandae fortiter incubuit, ausus ipsos mortis illius impetus morari quae pede pulsata aeque "pauperum tabernas regumque turres." Ergo nostro quoque titulo decorem virum titulis iam plurimis aliunde ornatum, Baronetum illustrem, Wilelmum Jenner.

Sir WM. GULL, Bart., F.R.S.—Pulchrum sane est genus illud vitae quod θεωρητικὸν Graeci nominant; pulchrius fortasse quod idem πρακτικὸν appellant; omnium, nisi fallor, pulcherrimum, humano certe generi utilissimum, et θεωρίαν et πρᾶξιν mutua quadam societate inter sese coniunxisse. Cuius rei egregium exemplar in hoc viro hodie iuvat admirari, qui physiologiae scientiam intimam ad artis medicae usum cotidianum feliciter accomodavit. Talium virorum adventu, quotiens aegrotantium lectulis nova lux affulsit! Medicorum talium auxilio, quot et quantos viros ab ipso mortis limine ad vitam rursus vocatos vidimus! Vobis praesento Regiae Societatis Socium, e Regiis medicis unum, Baronetum insignem, Wilelmum Gull.

Sir GEORGE BURROWS, Bart., M.D., F.R.S.—Unum nostris ex alumnis, nostrarum scholarum umbræ hodie paulisper redditum, vultu quam laeto excipimus. Scilicet in hoc ipso senaculo, quinque et quinquaginta abhinc annis, e studiis mathematicis lauream insignem reportavit; deinde Collegii illius vicini socius electus est cuius inter conditores medicum illum Regium, Iohannem Caium, existissime gloriariur; postea, e nostris umbraculis egressus, etiam urbis magnae in luce laudem illustrem adeptus, non modo Regi Medicorum Collegii praeses saepe numero est creatus, sed illius quoque Reginae medicis ascriptus est quam usque ad hunc diem omnes et vivere et valere gaudemus. Vobis praesento Baronetum venerabilem, Georgium Burrows.

WM. BOWMAN, F.R.S.—Sequitur deinceps vir qui adhuc juvenis corporis humani penetralia intima curiositate minuta perscrutatus, illa quae a se ipso optime erant fundata, ab aliis animo magno reliquit extruenda. Ipse interim sese ad illam potius partem explorandam destinaverat, cuius auxilio ad ceteras investigandas felicitas usque erat; ad ipsum videndi sensum, ad ipsos oculos (ut ita dicam) oculos sustulit. Quid autem humanius quam hebescentem oculorum aciem rursus aciem effecisse? Quid, prope dixerim, divinius quam hominibus lumine orbatis lucem illam diei quae Dei donum primum est, totiens reddidisse. Duco ad vos Regiae Societatis Socium, Wilelmum Bowman.

Rev. S. HAUGHTON, M.D., F.R.S., *Fellow of Trinity College, Dublin*.—Venio ad nomen multiplex scientiarum laude illustratum, Professoris scilicet Dubliniensis, viri de studiis Theologicis, Geologicis, Zoologicis, Geographicis, Physicis, Mathematicis, Medicis denique, optime meriti. Ipsa autem "naturae rerum contemplatio," ut ait Celsus, "quamvis non faciat medicum, aptiorem tamen medicinae reddit." Omnia vero illa quae intra provinciae suae fines satis amplius includit, hodie saltem non modo orationis nostrae terminos artiores excedunt, sed temporis quoque angustiis iniquis excluduntur. Praesento vobis virum reverendum, qui fere nullum scientiarum genus intactum, nullum inornatum reliquit, Samuelem Haughton.

JOSEPH LISTER, F.R.S.—Quam multa, quae antiqui temeraria quadam coniectura fortuito asscuti sunt, nunc demum hodiernae scientiae experimentis vera esse constat. Ipse Lucretius olim divinaverat morbos idcirco generari "nimium quia sunt multarum semina rerum, et satis haec tellus nobis caelumque mali fert, unde quaest vis immensi procreare morbi." Atqui usque ad recentem memoriam incerti errabant medicis, ut eiusdem verbis utar, "expertes opis, ignari quid vulnera vellent." Nunc autem, uti nostis ipsi, per Europam totam, chirurgi fere omnes Machaonis nostri praeceptum illud praeclarum sequuntur, scilicet in vulneribus sanandis nihil magis prodesse, quam noxia illa rerum primordia summa cura arcere. Itaque cum tanto viro nos quoque libenter foedus icimus, dextraeque illi intrepidae dextram hospitio iungimus. Duco ad vos Iosephum Lister.

Dr. DENIS C. O'CONNOR, M.D., *Professor of Medicine, Queen's College, Cork*.—Magnum est insularum Britannicarum medicis in consilio delibitantibus summa cum dignitate praefuisse; felix quoque suo optime functum, successoris dignissimo munus reddidisse. Quis autem nobis debet esse coniunctior quam is qui nuperime reipublicae medicae gubernacula illa, uni e professoribus nostris tenenda tradidit? Illi vero e portu iam solventi, nemo magis favere potest quam hic qui ex alto in portum invectus est, ipse in Collegio Professor prope celeberrimum Hiberniae portum posito. O si unquam inter memora portui illi vicina, lapidem illum fabulosum, saxum illud eloquentiae, oratori vestro con-

tigisset oculari; tum profecto tot et tantos viros ea qua par erat eloquentia laudare potuissent. Ceterum, utcumque haec sunt, praesentio vobis Professorem venerabilem, Praesidem optimum, Doctorem O'Connor.

JOHN SIMON, C.B., F.R.S.—Adest deinceps vir de sanitate populi nostri tuenda atque augenda optime meritis. Quod si huius viri laudes, uti meministi, etiam ab exteris beneficibus palam praedicatae sunt, quanto magis ab ipsis Britannis tot beneficiorum auctorem animo gratissimum commemorari necesse est. Ipsum Ciceronem in libris illis quos de legibus composuit, scripsisse recordamur, populi salutem supremam esse legem. Ergo iure optimo legum Doctorem hodie creamus virum de populi salute praeclare meritum, virum litterarum quoque laude insignem, Iohannem Simon.

ANDREW WOOD, M.D., F.R.S.E.—Claudit seriem Andreas Wood, vir ex Athenis illis Caledonicis Academiae nostrae spatii allatus, quem non modo Minervae Medicae sed ipsarum etiam Musarum inter cultores esse iuvat. Meminit fortasse Vergilianum illum lapim cui Apollo "citharam dabat," "scire potestates herbarum usumque medendi" maluisse; sed suo ipsius exemplo probavit "dulce" illud "laborum lenimen" cum arte medendi esse consentaneum. Recordatur certe Horatium illum suum, Apollinem ipsum laudare non modo quod "salutari levet arte fessos corporis artus," sed etiam quia "novem Camoenis acceptus" sit.

Restat ut vos omnes qui sociorum vestrorum laudes tanta benevolentia audivistis, tanto planius exceperitis, Academiae nomine valere iubeamus. Ipsum Medicinae Patrem dixisse meministi, vitam esse brevem, artem longam. Vos igitur, quorum arte vita totiens longior facta est, ipsi diu felices vivite. Vos qui omnium optime nostis, non vivere sed valere esse vitam,—vos, inquam, mox a nobis abituri, rursus forsan redituri, ipsi interim omnes valete.

THE SERVICES.

ARMY MEDICAL DEPARTMENT.—The officers of the department ordered to proceed to India to increase the establishment are as follows:—Surgeons-Major W. Ashton, E. J. Boulton, C. M. Douglas, C. A. Innes, H. M. Macbeth, Thomas Murtagh, and M. L. White; Surgeons A. L. Browne, J. D. Day, C. E. Dwyer, C. R. Egan, Richard Exham, S. J. Flood, W. C. Grant, W. R. Henderson, David Leckie, Robert H. Robinson, O. S. Ward, James Watson, and D. Williams.

ADMIRALTY.—Surgeon James Dunlop, M.D., has been promoted to the rank of staff-surgeon in Her Majesty's Fleet, with seniority of the 13th inst. Deputy Inspector-General John Cotton, M.D., has been appointed to Plymouth Hospital, vice McShane, retired; staff-surgeon J. Strickland to the *Himalaya*.

Correspondence.

"Audi alteram partem."

"REGINA v. INGLE : MEDICO-ETHICAL ASPECTS OF THE CASE."

To the Editor of THE LANCET.

SIR,—Your third "leader" on the nursing case at Guy's calls for a few words of information, which may be supplied without touching upon the question which has to be reserved for the Censors' Board of the College of Physicians. The clinical report and other facts shall, at the appropriate time, be placed in full before the profession. You say: "The first question that arises is whether the step taken in this most deplorable case was determined upon at a formal meeting and after a general consultation of the medical staff, or was the independent act of Dr. Pavy, who, considering the circumstances, felt himself unable to give the usual certificate of death?"

The first step in the case consisted of the patient's statement to me, and thence followed the succession of events that occurred. At my visit, on Monday, July 5th, I had not the slightest idea that anything particular had happened in the ward until I reached the patient's bedside. The complaint was then made to me about the bath administered in the morning. The house physician and several students were standing round the bed. After hearing what the patient had to say, I sent, without a moment's hesitation, for the sister, who was at the time in another part of the ward, and told her what had been mentioned, and said that the complaint must be fully inquired into. I also requested the house-physician to obtain all the particulars he could and lay them before me at my next visit on the Wednesday, in order that I might place the matter in the shape that might be found requisite, before the authorities of the hospital. This was the starting-point of all that followed, but at the

time I had not the most remote idea that the matter would culminate in anything extending beyond the hospital walls.

At my visit on the Wednesday the case had assumed a more serious aspect. Several bruises had been discovered on the patient's body, and the house-physician had, in his weekly report, already mentioned the circumstance to the treasurer. It was afterwards also officially mentioned by me with the result that on the following Saturday an investigation was conducted which led to the dismissal of the nurse. Meanwhile the patient grew worse. On Thursday (July 8th, three days after the bath) I expressed the opinion in the ward and to some of my colleagues that tubercular inflammation of the brain had set in, and in my communication to the treasurer, written on the evening of July 8th, I said: "I feel that the patient has received a shock, from which she will not recover. I found her very ill at my accustomed visit on Wednesday—so ill as to lead me specially to go to the hospital in the evening to see her. I found her worse this afternoon, and I hope I may be mistaken, but fear she is in a state to give little ground for hope of rallying." It was the diagnosis of tubercular inflammation of the brain which gave the foundation for my writing thus. The patient died during the night of the 21st, or 13 days afterwards. The husband, I was informed, had spoken of taking out a summons against the nurse for the ill-treatment of his wife, but this was not done. Dr. Steele, the superintendent, can give the information of how the inquest was brought about. The physician has nothing to do with signing the certificate of death. All that I can state is that I received intelligence of the death from the house-physician about 12 o'clock on Thursday the 22nd, and went to the hospital in the afternoon to attend the post-mortem examination. I was told that Dr. Steele had been in consultation with the coroner during the morning, and that the husband and friends of the deceased had also been with him; and before I left it was intimated to me that the holding of an inquest had been decided upon. This is how the matter stood, but I had, some days previously, said to Dr. Steele in passing through his office that if the patient died I considered justice demanded that an inquest should be held, and I must also say that I expressed this opinion to my colleagues and one or two other members of the profession to whom I spoke about the case; but in no way either directly or indirectly did I communicate with the husband or friends upon the subject. Whatever was said or done by them certainly arose from their independent action.

A great deal more was made of hysteria in connexion with the case at the trial than it was entitled to receive. The nurse in the inquiry before the treasurer had excused herself by saying that she had been given to understand that the patient was suffering from hysteria, and that she thought she was only putting into force the proper treatment. This defence was not less ingenious than it was surprising to me; but, as I had spoken of the indefinite pains complained of at the time of admission as probably hysterical, I felt I ought to make allowance; and, therefore, did not express myself at the trial in the manner I am now at liberty to do. The patient was in the hospital with no decided alteration in her state for very nearly a month before the bath was administered. It was only at first that anything was said about hysteria. I doubt if the term was made use of in relation to the patient's case during the last three weeks of the period named. Certainly at no time was the case really regarded as one of hysteria, nor was any word uttered by me that could give justification for the treatment of hysteria to be applied by the attendants in the ward. The prescription paper suspended at the head of the bed contained, written after the word disease, "Phthisis left side," and nothing about hysteria. The patient was throughout in a weak and delicate state of health. The aspect and general condition afforded testimony which no one, much less an experienced nurse, could possibly mistake. I am quite sure the sister of the ward received from me—I may say in a special manner in this particular case—the impression that gentle and careful management was required. But a few days before the bath I had said, "See if you cannot get this patient up for an hour or two in the evening, she will only grow weaker by remaining in bed," and the last time I saw her before the bath, in consequence of what was mentioned about pain in the left leg, I said to the sister, "I must leave it to you to exercise your judgment as to whether you consider the patient fit to be got up." Had the sister been appealed to by the nurse about putting into practice any treatment for hysteria, I am

perfectly satisfied she would have discountenanced it in the strongest terms. I think I have said enough to show what the excuse upon the ground of applying treatment for hysteria was worth, and it struck me with astonishment when I heard that such a plea had been advanced at the inquiry before the Treasurer.

I am, Sir, your obedient servant,

F. W. PAVY.

Grosvenor-street, August 18th, 1880.

CASES OF WOOLSORTERS' DISEASE.

To the Editor of THE LANCET.

SIR,—As woolsorters' disease is at present attracting the attention of the profession, perhaps the following cases may interest some of your readers:—

CASE 1.—James G—, aged forty-nine years, a sorter of inferior mohair locks at the Black Dyke Mills, Queensbury. I was called in to see the deceased on the morning of the 23rd July. He stated that he had been at work the day previous, but had not felt quite well for some days. He complained of great weakness, cough, and difficulty of breathing. His pulse was almost imperceptible; respiration about 30 per minute, and laboured; temperature in the axilla 102·5° F.; perspiration very abundant. He was quite conscious, and remained so up till death. The chest was resonant in front, but dull on both sides behind. Bronchial râles were everywhere distinct. Heart-sounds normal, but very weak. I ordered him ammonia, brandy, strong broths, and milk, but he died two hours after my visit.

Dr. Spears and I made an examination of the body nine hours after death. The following were the points observed:—A dark purple discoloration of the ears, arms, fingers, and front part of the scrotum; rigor mortis well marked. Brain slightly congested, the ventricles containing more fluid than normal. Pericardium contained about three ounces of clear straw-coloured fluid. Heart healthy, left ventricle firmly contracted, right ventricle filled with dark fluid blood. The structure of both lungs apparently healthy, each pleural cavity containing a large quantity (about two quarts) of clear serum. A number of extravasations of blood beneath the mucous membrane of the trachea and bronchi, most marked at the bifurcation of the trachea. Bronchial glands enlarged, soft, and easily broken down; on section were filled with what appeared to be dark blood. Minute extravasations beneath the mucous membrane of the stomach. Liver, spleen, kidneys, and intestines healthy. The blood everywhere fluid, and of a dark colour. The connective tissue throughout the body of a soft, gelatinous consistence; this was most marked in the connective tissue of the mediastinum.

CASE 2.—Samuel F—, aged thirty-three years, unmarried, and had previously enjoyed good health; was sorting similar material. This case was under the care of Dr. Fawthrop. Deceased began to complain of pain in the chest, cough, and dyspnoea on the 24th July. He was seen by Dr. Fawthrop on the evening of the 26th July. He was then suffering from what appeared to be pneumonia of the right lung. The pulse was 126 per minute, temperature 103° F.; respiration hurried and laboured; great restlessness and sleeplessness. He died on the 28th.

An examination, which was made twenty-nine hours after death, revealed the following appearances:—Rigor mortis well marked; discoloration of the skin similar to that found in the first case. Brain apparently normal, except for a slight extravasation of blood from the choroid plexus of each lateral ventricle. Pericardium contained a good deal of clear serum. Heart normal in structure; the lining membrane of the ventricles, semilunar valves, and commencement of the aorta and pulmonary artery stained a bright cherry-red colour. The right pleural cavity contained four pints of serum. Right lung congested, and a little inflammatory exudation into the lower lobe. Left lung quite normal, except that its pleural cavity had been obliterated by a previous attack of pleurisy. Lymphatic glands pertaining to the right lung very much enlarged, soft, and contained a dirty-brown thick fluid; those on the left side normal. The mucous membrane of the trachea and bronchi of a dark purple colour, with here and there a minute extravasation beneath it. Spleen of normal size; perhaps a little softer

than usual. Stomach congested. Liver, kidneys, and intestines healthy. Blood dark and fluid.

In both cases blood drawn after death, as well as fluids taken from the pericardium, pleural cavity, and spleen, were examined by Drs. Bell and Jackson, myself, and others, and found to contain the bacillus anthracis in large numbers. In both these cases death may fairly be attributed to the occupation of the individual, inferior mohair locks being among the most dangerous class of materials to the wool-sorters, containing, as they do, a large amount of fleeces derived from animals which have died from anthrax. These fleeces are found to contain the bacilli anthracis in large numbers. Being packed in bags they are imported still retaining their vitality unimpaired. When the bags are opened and the fleece sorted, fine hairs containing the bacilli anthracis rise in the air, are inhaled, and supposed to enter the blood by the lungs. Once in, they multiply rapidly, and set up changes which too often end in the death of the infected individual. I have lately met with two or three suspected cases of this disease which ended in recovery. In these cases the bowels acted freely, and although there were great prostration, restlessness, &c., a recovery took place in a few days. In none of these cases were the lungs affected, and, of course, it will always remain a matter of doubt as to whether they were true cases of anthraxæmia or not. Blood taken from the arm showed no bacilli, but this likewise obtains in cases where the patient dies and the bacilli are found after death.

No special treatment has, I believe, as yet been found successful in the bad forms of this disease. In the cases which recovered the treatment adopted was saline purgation; chloral hydrate and bromide of potash, the two latter to combat the restlessness.

I am, Sir, yours, &c.,

SINCLAIR WHITE, M.D., M.Ch.

Bradford, August 2nd, 1880.

CREMATION OR BURIAL?

To the Editor of THE LANCET.

SIR,—After hearing a paper on Cremation last Thursday in the Section of Public Health, at the Cambridge Meeting, many of the members present signed the following address to the Home Secretary:—

“We, the undersigned, Members of the British Medical Association assembled at Cambridge, disapprove of the present custom of burying the dead, and desire to substitute some mode which shall rapidly resolve the body into its component elements by a process which cannot offend the living and may render the remains absolutely innocuous. Until some better mode is devised, we desire to promote that usually known as cremation. As the process can now be carried out without anything approaching to nuisance—and as it is not illegal—we trust the Government will not oppose this practice, when convinced that proper regulations are observed, and that ample guarantees of death having occurred from natural causes are obtained than are now required for burial.”

I have been informed that many more members would have signed this address if they had heard of it or seen it, and it is probable that members who were not at Cambridge, or others not members of the Association, might wish to sign it before it is presented. I shall therefore be obliged if you will allow me to make known through your columns that I shall be glad to receive by note or post-card the name of any gentleman who may desire to append his signature to the memorial.

I have the honour to be, yours &c.,

T. SPENCER WELLS.

Upper Grosvenor-street, W., August 17th, 1880.

INDIAN MEDICAL SERVICE PENSIONS.

To the Editor of THE LANCET.

SIR,—I am a surgeon-major in the Indian army of over twenty-two years' service, and should—as I fear will be the case—my health prevent my returning to India, I shall have to retire on a pension of £220, or as much of that as will remain after deduction of subscription to military and orphan funds and English income-tax.

Had every day of my service been spent in India I should

now be entitled to a pension of £292, but having been thrice obliged to take sick leave, the greater part of which is deducted from my service for pension, I am only entitled to the lower rate. I have had no leave in India, and none out of India except sick leave.

A medical officer of the British service is, on the completion of twenty years' service, the greater part of which has probably been in England or in temperate climates, entitled to a pension of £365; and, in his case, all leave is counted as service for pension.

Surely the man who has had to bear the burden and heat of the day in the scorching plains of India is entitled to *at least* an equally good retiring allowance when his health breaks down under the strain.

I trust you will use in behalf of the Indian Service the same able advocacy of our claims urged in your columns on behalf of the sister service, which tended so much to gain for its members the equitable pension rules which they now enjoy.

Yours truly,
SURGEON-MAJOR,
Senior Grade I.M.S.

MEDICAL NOTES IN PARLIAMENT.

In the House of Commons, on Thursday, the 12th inst. a copy was presented of an Order in Council, approving of additional regulations made by the Council of the Pharmaceutical Society of Ireland.

On Friday, a tabulated return was ordered, upon the motion of Mr. Hopwood, for the year 1847, and for each year from 1855 to 1878 inclusive, of the proportion per cent. of deaths from small-pox in England and Wales amongst infants of various ages up to ten years, and of the proportion of deaths among infants under one year, per million of births from each of the following causes: syphilis, scrofula, tabes mesenterica, skin disease, erysipelas, pyæmia and phlegmon, bronchitis, diarrhoea, atrophy and debility.—Lord F. Cavendish stated to Mr. Corbet that there had been no reduction in the grants to hospitals and infirmaries in Ireland. An apparent reduction in 1879 was due to an alteration in the period for which the account was made up.—Captain Aymer, on behalf of Mr. Grantham, asked the series of questions with regard to the compulsory retirement of Captain Chatterton, on a medical report, in January, 1869, which questions were printed in last week's LANCET. Lord Hartington, in reply, said he had no objection, for the satisfaction of the Honourable Member, to ask the Indian Government for a report on the case, but he must repeat that the case had been under the consideration of successive viceroys and secretaries of State, and he could not hold out any hope that the decision would be reversed. At the evening sitting, Mr. O'Connor Power called attention to the condition of the fever districts in the west of Ireland, with special reference to the bad state of the cabins. The hon. gentleman read copious extracts from the reports of the medical inspectors sent down by the Local Government Board, showing the squalid and unhealthy nature of the cabins, many of which consisted of one room, in which, besides the occupier's family, cows and pigs were kept. He also pointed out the references in the reports to the necessity for supplying the distressed population with a change of nutritious food. He admitted that, owing to the action of the Irish authorities the actual amount of disease had been much diminished, but urged that the insanitary condition of the dwellings required the serious and immediate attention of the Government, and that a competent medical staff should be organised and distributed over the districts affected by fever; and he concluded by moving a resolution to that effect. Mr. Sexton, in supporting the resolution, said the guardians in the west of Ireland were not fit to be trusted with the administration of the Poor Law. The most urgent want of the people was a change of food from Indian meal. He suggested that some of the veterinary surgeons who were kept by the unions should be got rid of, and qualified medical officers put in their place. After speeches from several other Irish members, Mr. Forster said the calamity and distress of this year would have one good result—in throwing a strong light upon the condition of the people in certain parts of Ireland. Probably, the county Mayo was about the worst, but parts of Galway were almost as bad. Admitting that the people were predisposed

to fever by bad sanitation and a want of sufficiently nourishing food, Mr. Forster said he believed they had now got over the stringent emergency of the crisis. Many of the suggestions of the mover of the resolution had been carried out, in supplying a change of food, an efficient medical staff, and a number of nurses, and highly encouraging results were now being reported. He had no objection to the resolution being adopted in a modified form, to the effect that the condition of the agricultural population of Mayo, Sligo, and Galway demanded the serious and immediate attention of the Government. Some further discussion ensued, in the course of which Dr. Lyons pointed out that a reform of the dwellings of the poor could only be brought about gradually. He wished to say a word with regard to the general medical service. He was sure Mr. O'Connor would not wish to throw any doubt upon the assiduity, ability, and zeal of the medical gentlemen who had charge of the sick poor in the fever districts. The medical inspectors had stated in the most cordial terms their approval of the manner in which the local practitioners in charge of dispensary districts had carried out their duties, remarking particularly upon the careful management of those gentlemen, and the readiness with which they exposed themselves, regardless of any risk. He could not believe that persons had had to go forty miles for dispensary relief, as had been stated. That must be an exaggeration; but it was a subject that required attention. He advocated the establishment of *depôt* hospitals in the villages during these fever outbreaks wherein the sick could be more successfully treated than in their wretched homes. Mr. O'Connor Power having accepted the suggestion of the Chief Secretary, the resolution, as amended, was agreed to.

On Monday, on the motion of Mr. Meldon, a return was ordered of the names of all medical officers of workhouses and dispensaries in Ireland who, since the passing of the Medical Officers Superannuation Act, 32 and 33 Vic. c. 50, have resigned their offices and applied to their boards of guardians for superannuation allowances under that Act, with the causes for such resignation; the ages and length of service as Poor Law Medical Officers of each person at date of resignation; the result of such application to the guardians; and the reason, if any, given by the said guardians for refusing the application.—Some discussion took place in Committee of Supply on the vote for the Broadmoor Lunatic Asylum. Mr. A. O'Connor complained that the salaries of the Broadmoor officers were much higher than those paid in the Dundrum Asylum, whilst the wages of the attendants were nearly double. Mr. Peel replied that year by year these estimates were being reduced. He did not think the salaries were excessive. A commission was now investigating the whole subject of Broadmoor. In answer to Mr. Briggs, the honourable gentleman stated that when the criminal lunatics were being transferred from Bethlehem to Broadmoor, one of them had become so much attached to the former place that he begged to be allowed to remain, and his request was granted. Mr. O'Connor, returning to the charge, contended that the attendants at Dundrum had double the work at half the pay of the Broadmoor attendants. They looked after seven patients apiece, whilst the Broadmoor attendants only looked after four apiece. The whole of the vote was extravagantly drawn up. For instance, books and newspapers cost £75 a year.—The Solicitor-General of Ireland mentioned that he had recently gone over the Dundrum Asylum and found it excellently managed.—Mr. Biggar moved to reduce the Broadmoor vote by £400, but the amendment was negatived, and the vote was agreed to.—A copy of revised rules for prisons in Scotland, under sanction of the Home Secretary, was presented.

On Tuesday petitions were received from Surgeon-Major Philip Warren Sutherland and Surgeon-Major Samuel Jardyne Wyndewe, for inquiry into their respective cases. Mr. McLaren presented the former petition, and Mr. Dick Peddie the latter, and both were ordered to lie on the table.—Petitions against the Vaccination Acts Amendment Bill continue to come in, notwithstanding the abandonment of the measure, and one was received to-day from the Hampstead Union.—Mr. W. Corbet gave notice that early next session he will "call attention to violations, not only in letter, but more in spirit, of the Charter of His Majesty King George the Second for erecting and endowing Saint Patrick's Hospital for Lunatics, Dublin, founded by the will of Dean Swift, and commonly called Swift's Hospital, and to all the circumstances connected with that institution"; and move a resolution,

Obituary.

WILLIAM WHITE WILLIAMS, M.D., F.R.C.P.

WE have to record the death of Dr. W. W. Williams, which happened on the 6th inst., at his house in Cheltenham, where, on the 2nd inst., he was suddenly seized with an attack of hemiplegia, from the effects of which he never rallied. He had for some years been in failing health, but not in a condition to cause any immediate anxiety to his family. Dr. Williams was born in April, 1815, and was thus in his sixty-fifth year. He was educated at the London Hospital, and he engaged for a few years in general practice in Oxfordshire, and subsequently at Hayes in Middlesex. Here he was attracted by the teaching of Dr. Conolly at Hanwell to the special study of mental disease, and in 1845 was appointed medical superintendent of the Gloucester County Asylum—his native county. He held this office till 1863, when he retired in ill-health, receiving from the Quarter Sessions a liberal pension, and the appointment of honorary consulting physician to the asylum. During his tenure of office at Gloucester the charity foundation was separated from the county funds, and the private patients transferred to the new Lunatic Hospital at Barnwood, which owed its origin and much of its early success to Dr. Williams's foresight and judgment, and of the Governing Committee of which he continued to the last a member.

Dr. Williams was also for many years honorary secretary of the Medico-Psychological Association. He shared with Mr. Gaskell and Mr. Wilks—both subsequently Commissioners in Lunacy—and with Dr. Bucknill, F.R.S., the early labours which built up, on Lord Shaftesbury's Act of 1845, our present English public asylum system, on the foundation-stone of the non-restraint system, which he had learnt from Dr. Conolly's teaching at Hanwell.

Subsequent to his retirement from office in 1863 Dr. Williams lived in Cheltenham, and to the last took the warmest interest in the progress of medical science. There were few new books he did not read, and the latest writings on psychological medicine found in him a diligent student. A man of retiring disposition, and with but a modest estimate of his own powers, his great gifts of organisation and industry were hardly known beyond the sphere of his daily work. Of blameless life, of warm domestic sympathies, and of unvarying hospitality, his family and his old trusted friends—like the writer of these few memorial lines—alone knew his full worth, or are able to measure their own great loss, and which, from the suddenness of the blow, they hardly yet know as they will, when, in the dull years to come, they begin to miss his wise and gentle counsel, and to long once more for his genial welcome.

Medical News.

UNIVERSITY OF LONDON.—The following candidates have passed the recent First M.B. Examination for Honours in the subjects indicated:—

ANATOMY.

FIRST CLASS.

Cooper, Geo. Fredk. (Gold Medal), St. Thomas's Hospital.

THIRD CLASS.

Evans, Charles Silvester, St. Thomas's Hospital.
Moline, Paul Frank, University College.
Martin, Sidney Harris Cox, B.Sc., University College.
Horrocks, William Heaton, Owens College.
Norvill, Frederic Harvey, King's College.

PHYSIOLOGY AND HISTOLOGY.

FIRST CLASS.

Price, John Alfred Parry (Exhibition and Gold Medal), Guy's Hospital.
Tunzelmann, E. W. von (Gold Medal), University College.
Halliburton, Wm. Dobinson, B.Sc., University College.

SECOND CLASS.

Horrocks, William Heaton, Owens College.
Equal merit. { Booth, Edward Hargrave, Guy's Hospital.
Martin, Sidney Harris Cox, B.Sc., University College.

THIRD CLASS.

Collier, Joseph, Owens College.
Evans, Charles Silvester, St. Thomas's Hospital.

CHEMISTRY.

FIRST CLASS.

Price, John Alfred Parry (Exhibition and Gold Medal), Guy's Hospital.
*Overend, Walker, B.Sc., St. Bartholomew's Hospital.
(* Obtained the number of marks qualifying for a Medal.)

SECOND CLASS.

Stephens, Lockhart Edward Walker, Guy's Hospital.

THIRD CLASS.

Spicer, Robert Henry Scanes, B.Sc., St. Mary's and Guy's Hospitals.

MATERIA MEDICA AND PHARMACEUTICAL CHEMISTRY.

FIRST CLASS.

Halliburton, Wm. D., B.Sc. (Exhibition and Gold Medal), University College.

SECOND CLASS.

Brooks, Walter Tyrrell, King's College.
Overend, Walker, B.Sc., St. Bartholomew's Hospital.
Wilkinson, Wm. Camac, B.A. Sydney, University College.

THIRD CLASS.

Equal merit. { Beverley, John Metcalfe, Owens College.
Price, John Alfred Parry, Guy's Hospital.
Faulkner, Joseph, St. Bartholomew's Hospital.
Adams, William Coode, University College.
Berry, James, St. Bartholomew's Hospital.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on Aug. 12th:—

Creswell, John Charles, Bromsgrove.
Newcombe, Frank, Derby.
Fotherby, Henry Arthur, Finsbury-square.
Oswold, Robert James William, Kennington-road.
Palmer, Harold Lewis, Haverfordwest.
White, Edwin Francis, Putney.

The following gentlemen also on the same day passed their Primary Professional Examination:—

Alexander Lane, Guy's Hospital; Ernest Llewellyn, London Hospital.

UNIVERSITY OF GLASGOW.—The following are lists of candidates on whom the degrees of M.D., B.M. & C.M., and B.M. were conferred by the University on July 29th:—

DOCTORS OF MEDICINE.

*Bryce, James, M.B., Scotland.	Hunt, Thomas, M.B., Scotland.
Denniston, Jas., M.B., Scotland.	Hutchison, Jas., M.B., Scotland.
Dun, Wm. G., M.B., Scotland.	Jones, Jas. Arthur, M.B., Wales.
Elder, George, M.B., Ireland.	Young, Thomas, M.B., Scotland.
Gemmell, Samson, M.B., Scotland.	

* Commended for Thesis.

BACHELORS OF MEDICINE AND MASTERS IN SURGERY.

Adam, Alexander, Australia.	Mackay, Hugh, Scotland.
Anderson, Matt. S., M.A., Scotld.	Macindoe, Alexander, Scotland.
Blyth, David, Scotland.	Macintosh, Malcolm, Scotland.
Bond, John, Scotland.	M'Crorie, Archibald, Scotland.
Boyd, James D., Australia.	M'Culloch, Allen, Scotland.
Brown, John T., Scotland.	M'Dougall, Hugh, Scotland.
Campbell, Walter Scott, Scotld.	M'Gregor-Robertson, J., M.A., Scot.
Campbell, William A., Scotland.	M'Kenzie, John, Scotland.
Davidson, Thomas, Scotland.	M'Lennan, Quintin, Scotland.
Dinsmore, Geo. H. J., England.	M'Leod, Donald, Scotland.
Fraser, William, Scotland.	M'Vean, John D., Scotland.
Gemmell, Thos. P., Scotland.	Martin, Alexander, Scotland.
Gilbert, Robert, Scotland.	Miller, Robert, Scotland.
Gilchrist, Robert M., Scotland.	Morison, Donald, Scotland.
Grant, David, Scotland.	Morton, Alex., M.A., Scotland.
Gregson, Thos. W., England.	Muir, James F., Scotland.
Gupta, Pyari Mohan, India.	Ochiltree, E. G., Australia.
Hogarth, And. A., M.A., Scotld.	Parmer, William F., India.
Inglis, David W., M.A., Scotland.	Picken, James, Scotland.
Johnston, Alex., Scotland.	Reid, John, Scotland.
Jones, Wm. Rees, Wales.	Ritchie, John, Scotland.
Kaye, James, Scotland.	Scott, George, England.
Kerr, J. G. Douglas, Australia.	Speirs, John L., Scotland.
Kilpatrick, Alex., Scotland.	Steven, John Lindsay, Scotland.
Kirkland, Robert, Scotland.	Stevenson, John, Scotland.
Kyle, David H., Australia.	Stewart, Alexander, Scotland.
Laing, Wm. A. G., England.	Stewart, Thomas, Scotland.
Ledingham, Alex. N., Scotland.	Tannahill, Thomas F., Scotland.
Liddle, Wm. T., Scotland.	Taylor, Robt. G., C. of Good Hope.
Love, James K., Scotland.	Topping, John P., Scotland.
Macaulay, John T., Scotland.	Wilson, James A., Scotland.
Mackay, Alex. D., Scotland.	Walker, John M., Scotland.

BACHELORS OF MEDICINE.

Babbie, William, Scotland.	Palmer, Benj. A., Ireland.
Brown, Wm. H. J., Scotland.	Pollock, Chas. Fred., Scotland.
Cluckie, Niven Gordon, Scotland.	Rankin, Guthrie, Scotland.
Macintyre, Alexander, Scotland.	Turnbull, Ridley, England.

The following gentlemen were named as entitled to Honours, to High Commendation, and to Commendation, on account of distinguished merit at the various examinations for the degrees of M.B. and C.M.:—

HONOURS.

Hogarth, Andrew A., M.A.	Robertson, Joseph M'Gregor, M.A.
Steven, John Lindsay.	

HIGH COMMENDATION.

Inglis, David W., M.A.

Pollock, Charles Fred.

COMMENDATION.

Anderson, Matthew S., M.A.

Blyth, David.

Fraser, William.

Gilbert, Robert.

Grant, David.

Love, James K.

McDougall, Hugh.

Mackintosh, Malcolm.

Mackay, Hugh.

Martin, Alexander.

Morton, Alexander, M.A.

Palmer, Benjamin A.

Rankin, Guthrie.

THE LIBRARY of the Royal Medical and Chirurgical Society was closed on Monday, August 16th, and will be reopened on Thursday, September 16th.

THE salary of Mr. T. L. Gentles, L.F.P.S. Glas., medical officer for the southern district of the Derby Union, has been increased from £80 to £100 a year.

SIX CHILDREN and a servant, belonging to a household in Barnsley, were recently attacked to a serious extent with symptoms of irritant poisoning after partaking of corned beef which had been enclosed in a 2-lb. tin in the ordinary manner.

A ROYAL WARRANT has been promulgated in reference to the promotion of army veterinary surgeons for distinguished service. It provides that "in a case of distinguished service a veterinary surgeon, if qualified, may be promoted to the rank of first-class veterinary surgeon without reference to seniority."

THE FRENCH HOSPITAL.—The French Ambassador, M. Challemeil-Lacour, accompanied by the Comte de Florian, of the French Legation, paid a visit on the 14th inst. to the French Hospital and Dispensary, Lisle-street, Leicester-square.

WEST OF ENGLAND SANATORIUM.—At the annual meeting of the friends of this institution, held at Frome on the 11th inst., the report read showed that 719 patients had received the benefits of the charity, as compared with 638 in the previous year. The receipts for the past twelvemonth were £2037 18s. 8d., and the expenditure (with an investment of £50) £2122 17s. 4d.

REQUESTS TO MEDICAL CHARITIES.—Mr. Johnston, W.S., bequeathed £100 to the Royal Infirmary, £25 to the General Dispensary, £25 to the Hospital for the relief of persons suffering under infectious disease, all of Aberdeen; and £50 to the Edinburgh Royal Infirmary. By the will of Mr. Henry Crawter the National Hospital for the Paralysed and Epileptic becomes entitled to £200. The late Mr. Hugh Wardlaw of Belfast has bequeathed £100 per annum to the Belfast Royal Hospital, £50 per annum to the Belfast Charitable Society, and £50 per annum to the Ulster Institution for promoting the Education of the Deaf, Dumb, and Blind.

LONGEVITY IN ENGLAND.—The mortality returns for England in the year 1878, which have recently been completed, record the deaths of 230 men and 510 women registered as ninety-five years old and upwards when they died. Twenty-four of the men and sixty-four of the women had reached a hundred and upwards, viz., twelve males and twenty-seven females, 100 years; five males and thirteen females, 101; two males and eight females, 102; three males and seven females, 103; one male and four females, 104; 1 male and 4 females, 105; and one female who died in the Luton district, 106. Eight of these centenarians, one male and seven females, died in London districts.

A NEW CONVALESCENT HOSPITAL FOR PLYMOUTH AND DEVONPORT.—Up to the present time there had not been any provision for convalescent patients in the neighbourhood of Plymouth. To meet this urgent want a house has been purchased at Plympton, which is situated about five miles from Plymouth, on the skirts of Dartmoor. It is well placed upon the side of a hill in a healthy, airy situation, and has a small garden attached, where patients may sit and inhale the pure air from the moor, and yet be sheltered from the east wind. The house has been purchased, enlarged, fitted, and furnished at the sole cost of Miss Middleton, of Plymouth, a lady well-known in that town as a benefactor of the poor. She has placed the establishment in the hands of trustees, and two sisters of charity, who have had considerable experience in the convalescent house at Walton, near Cliefden, are now in charge. There is accommodation for ten patients of the female sex, and the medical men of Plympton,

Drs. Aldridge, Ellery, Miles, and Stamp have undertaken the medical charge. It is hoped that the House of Rest, or convalescent hospital, may prove of service to a numerous class of young women who are engaged in business, and who, from overwork or other causes, may require rest and change of air more than medicine for their restoration. Surgical cases will also be admitted, and it would therefore be a great boon to the general hospitals in Plymouth and Devonport if each had a bed in the House of Rest at their disposal. As the Home will be kept open all the year round, it will be available for cases of threatening phthisis which might be sent from the northern towns, the climate of Plympton being very similar to that of Torquay. As there is no endowment, the work will have to depend for support upon the subscriptions and donations of the charitable, and such assistance is being earnestly solicited by the committee. Subscribers of one guinea will be furnished with a letter, which will enable them to send a patient for a period of three weeks, the patient paying 3s. per week. Patients will also be admitted on payment of 12s. per week on the recommendation of a medical man.

Medical Appointments.

Intimations for this column must be sent DIRECT to the Office of THE LANCET before 9 o'clock on Thursday Morning, at the latest.

BROWN, A. S., M.R.C.S.E., L.S.A., has been appointed House-Surgeon to the Warneford Hospital, Leamington.
 CONSTABLE, J., M.D., C.M., Leuchars, has been appointed Medical Officer and Public Vaccinator for Dairsie, vice J. W. R. Mackie, M.D., deceased.
 DONKIN, W. F., M.A., has been appointed Public Analyst for the County of Wilts. Remuneration by fees.
 ELLIOTT, H., M.R.C.S.E., L.S.A., has been appointed House-Physician to the North Staffordshire Infirmary, Hartshill, Stoke-upon-Trent, vice Shaw, resigned.
 FINEGAN, A. D. O'C., L.K.Q.C.P.I., R.C.S.I. L.M., has been appointed Assistant Medical Officer to the St. George's-in-the-East Infirmary and Workhouse, vice W. J. Sprott, resigned.
 FORSYTH, R., M.D., C.M., has been appointed Medical officer of Health for Drighlington, Yorkshire.
 FRASER, G. B., M.R.C.S.E., L.S.A., has been appointed Honorary Medical Officer to the West of England Sanatorium.
 HACON, W. E., L.R.C.P.L., M.R.C.S.E., has been appointed Resident Medical Superintendent of the Christchurch Lunatic Asylum, Canterbury, New Zealand.
 HALL, Mr. T. L., has been appointed House-Surgeon to the Bridgnorth Infirmary and Dispensary, vice Gray, resigned.
 HAYES, T. E. D., L.K.Q.C.P.I., M.R.C.S.E., L.S.A., has been appointed Medical Officer to the Hawkhurst District of the Cranbrook Union.
 JACOB, E. H., M.A., M.D., has been appointed Honorary Physician to the Leeds Fever Hospital.
 MARSH, C. J., M.R.C.S.E., has been appointed Medical Officer for the Second District of the Yeovil Union, vice Garland, resigned.
 MELLER, C. M., M.D., M.R.C.S.E., L.S.A., has been appointed Medical Officer to the Carisbrooke District of the Isle of Wight Union.
 MILNE, T. M., M.D., has been appointed Medical Officer of Health for the Borough of Accrington, vice Ewart, resigned.
 ORFEUR, C. H., M.R.C.S.E., L.S.A., has been appointed Medical Officer to the Workhouse of the Bedminster Union.
 PRICHARD, J. E., B.A., M.B., M.R.C.S.E., L.S.A., has been appointed Resident Medical Officer to the Swansea Hospital, vice Phillips, resigned.
 ROXBURGH, R., M.B., has been appointed Honorary Consulting Physician to the West of England Sanatorium, vice J. J. E. Willmott, M.B., resigned.
 STONHAM, Mr. C., has been appointed Obstetric Assistant to University College Hospital.
 TICEHURST, C. S., M.R.C.P.E., &c., has been appointed Surgeon to the Petersfield Cottage Hospital, vice T. Moore, resigned.
 VLELAND, C. J., M.R.C.S.E., L.S.A., has been appointed House-Surgeon and Secretary to the General Infirmary, Hertford, vice G. H. Cressey, resigned.
 WRIGHT, A. H., M.D., has been appointed Associate Lecturer on Physiology in the Toronto School of Medicine.

Births, Marriages, and Deaths.

BIRTHS.

AIKMAN.—On the 30th ult., at New-street, Guernsey, the wife of John Aikman, M.D., of a daughter.
 BOWES.—On the 12th inst., at Berry Wood, Northamptonshire, the wife of J. Ireland Bowes, M.R.C.S.E., of a son.
 DAVIDSON.—On the 17th inst., at Priory-row, Coventry, the wife of Charles Davidson, M.D., of a son.
 GOODHART.—On the 12th inst., at Hervey-road, Blackheath, the wife of James F. Goodhart, M.D., of Weymouth-street, Portland-place, W., of a son.
 POWELL.—On the 14th inst., at Bromyard, the wife of Wm. Powell, M.R.C.S.E., of a son.
 STEVENS.—On the 16th, at High-street, Stoke Newington, N., the wife of A. Felix Stevens, M.D., of a daughter.

MARRIAGES.

HENTSCH—HORA.—On the 1st inst., at St. Giles's, Camberwell, John Page Hentsch, M.R.C.S., of The Terrace, Camberwell, to Edith, eldest daughter of Winfield Hora, Esq., of Camberwell.

MAYBURY—CURTIS.—On the 18th inst., at the Parish Church, Porchester, by the Rev. S. Lidbetter, Vicar of St. Mark's, Portsea, assisted by the Vicar, the Rev. T. Knight, Aurelius Victor Maybury, M.D., fourth son of William Augustus Maybury, Esq., Surgeon, Cedar Lodge, Frimley, Surrey, to Mary Elizabeth, eldest daughter of George Curtis, Esq., J.P., of Porchester.

MESSER—BELCHES.—On the 11th inst., at St. James's Church, Plymouth, Adam Brunt Messer, M.D., Fleet Surgeon, Royal Navy, to Elizabeth Mary, youngest daughter of Peter Belches, Esq., Commander R.N.

MYERS—BARTLETT.—On the 18th inst., at St. Paul's, Camden-square, N.W., by the Rev. Thomas Moore, Henry Reynolds Myers, Surgeon, to Laura Isabelle Bartlett, fourth daughter of Mrs. Thos. Boulton, of Gweedore House, Lee, Kent, and widow of the late Stephen Bartlett, Esq., of Belsize, Hampstead, N.W. No cards.

ROGERS—MABYN.—On the 7th inst., at St. Mark's, Myddelton-square, E.C., J. F. Rogers, L.R.C.P., M.R.C.S., to Eliza Coulson, daughter of the late George Maby, Esq., Bath.

ROUTH—ROUTH.—On the 14th inst., at the Parish Church, St. Mary-lebone, Amand Jules McConnel, M.R.C.S., L.R.C.P.L., eldest son of Dr. Routh, of Montagu-square, London, to Blanche Rothwell, daughter of the late Richard Routh, Esq., of Constantinople.

DEATHS.

DAVIS.—On the 16th inst., at Conie Brae, West Malvern, Henry Davis, M.D., F.R.C.S., formerly of Putney, aged 70.

HERBERT.—On the 11th, at Markyate-street, near Dunstable, Jonas Travers Herbert, L.R.C.P.Ed., L.R.C.S.Glas., aged 39.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Local papers containing reports or news-paragraphs should be marked.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

Lectures, original articles, and reports should be written on one side only of the paper.

We cannot prescribe, or recommend practitioners.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET to be addressed "To the Publisher."

THE BOARDING-OUT SYSTEM.

THE benefits attending the boarding-out of pauper children are distinctly affirmed and set forth in a report recently issued by a committee appointed by the Leeds Board of Guardians to inquire into the system as carried out in that union. They state that the success of the scheme has fully answered their expectations, and they confidently point to the children in the homes in which they have been placed for confirmation of the favourable opinion expressed in the report. Before being sent out, the children undergo a careful medical examination, and no child is allowed to be received until a certificate of fitness has been signed. Great care is taken to select healthy homes with persons of good character and habits, and the committee believe their efforts to secure these essentials have been so far successful. The average cost per head of 86 children thus boarded out, including maintenance, school and medical fees, and clothing, is estimated at 5s. 3d. per week.

Dr. J. Brown Sim will find the articles referred to in THE LANCET of May 18th and 25th, 1878.

Ambulance.—We were not aware of the existence of the Society named.

"RUNNING" IMPULSE IN EPILEPSY.

To the Editor of THE LANCET.

SIR,—Last year, when acting in association with Dr. Thomson, of Peterborough, I met with what was to me an unusual case of epilepsy. I should be glad to know if any of your readers have seen the seizure take a similar form.

A. W.—, aged twenty, labourer, employed in a brick-field near the town, while engaged in his ordinary occupation, suddenly became unconscious, and appeared to be seized with an irresistible impulse to run; the load he was carrying dropped from his shoulder, and after running about two hundred yards he fell into a pit half full of water, which happened to be in his way, and had it not been for the timely help of a fellow-workman the case would have ended in drowning. As it was, the man had the appearance of prolonged immersion, and required some care to "bring him round." I was informed that the patient had been subject to these attacks at intervals for some years, and that only six weeks previously he ran a distance of seven miles, when he was stopped on the road, and conveyed back to Peterborough. After resting an hour or two to overcome the fatigue of the attacks, work was usually resumed, provided no accident occurred.

The act of running can scarcely be looked upon as a form of aurage because there was no subsequent spasm, either tonic or clonic.

I am, Sir, yours truly,
J. D. MILLER, M.B. Edin.

Brampton, Cumberland, Aug. 7th, 1880.

NEW SYDENHAM SOCIETY.

THE Report of this Society presented to the twenty-second annual meeting, after enumerating the works issued in 1879, announces the probable series for the current year as follows:—1. A third fasciculus of the Society's Lexicon (already out). 2. The fifth and concluding volume of Hebra's Treatise on Skin Diseases, with index to the whole (already out). 3. Koch's Researches on the Etiology of Diseases consequent on Wound Infection. 4. A third fasciculus of the Society's Atlas of Pathology, comprising Diseases of the Liver. 5. A fourth fasciculus of the Lexicon. The Council has adopted for reprinting, the classical Treatise of Dr. Stokes on Diseases of the Chest. This work, which has been always held in very high estimation by all authorities, has been for some time out of print. It will be edited for the Society, with short annotations &c., by Dr. Hudson, of Dublin. It has also been decided to edit for the Society a selection from the works of Duchenne, and Dr. Vivian Poore has, at the Council's request, undertaken the preparation of the work. The translation of Professor Charcot's Lectures on the Diseases of Old Age, and on certain Chronic Maladies, has been decided on. The work has been placed in the hands of Mr. William S. Tuke. The preparation of the Society's Lexicon is, in the hands of its editors, Mr. Power and Dr. Sedgwick, progressing satisfactorily and as rapidly as the difficulties of the task permit. Three fasciculi have been issued, and another is just ready. It is to be distinctly understood that the fasciculi of this work are always issued as soon as ready. The Council is prepared to devote to it any portion of the year's income that may be requisite, and nothing but the onerous nature of the editors' task will be allowed to delay its publication. The balance in hand at the close of the year was £1367 1s. 9½d.

M.R.C.S. Eng.—The facts are very important, and should be communicated to any Corporation which may give its diploma to the person in question; but we cannot publish them.

X. Y. Z.—We have had a long correspondence on the subject recently.

THE UPPER ENGADINE, ST. MORITZ.

To the Editor of THE LANCET.

SIR,—Fashion has been charged as the ruling element in making the Upper Engadine a place of such well-known resort to invalids. If so, fashion for once is largely in the right. I have just returned from a sojourn there of eighteen days, ending July 17th, and can verify the accredited health-giving character to this place. During our stay we had rain for a portion of three days, several violent thunderstorms, particularly at night. The days were warm, the evenings and nights cold, necessitating extra covering—in fact, a hot-water bottle to the feet of a visitant is occasionally not an unacceptable adjunct to preparation for sleep. This is not peculiar to St. Moritz, but applies generally to all Alpine regions. Taking into account the altitude of St. Moritz, 5500 feet above sea-level, its temperature is as high as many places from 1000 to 2000 feet lower. The absolute dryness of the air; the diminished barometrical pressure, which is pretty even during summer and winter; the highly electrical condition of the atmosphere; the continuous air-currents which sweep through the valley, together with a universally increasing appetite and a corresponding digestion, form healthmates of no ordinary kind. In winter air-currents are less—in fact, there is hardly any wind, and the only disturbers of the place are thunderstorms. Consumption in the Engadine is unknown.

The waters, containing iron and soda salts, and also being freely charged with carbonic acid, are of an agreeable kind, and, like all waters with such surroundings, play good secondary parts as restorers of health. The enjoined rules for drinking the water and taking the baths are of the greatest moment to many who never observe rules; and, if residents at the "kurhaus," sleep is out of the question after 7 A.M., when a well-arranged band begins its programme. The cases best suited for the Engadine are those of anemia and convalescence. Rheumatic cases (I speak in this personally) may return as they went; if with a short probation. I should not under any circumstances suggest or sanction an invalid going to the Engadine for a period less than a residence of one or two months. The necessary five days' journey each way cannot otherwise be compensated for.

The Engadine has been charged with harpies, starvation, and barrenness. Harpies will hang on wealth, and that which belongs to the English spoils the pristine beauty of every place it touches. Starvation must be unknown where numberless hotels vie with each other in the moderateness of their charges and the profuseness of the table. Surely from 10 to 15 francs per day inclusive, when the whole season is only from July 15th to September 15th, cannot be considered high charging.

In regard to the selection of locality, I chose the village itself, which stands about 150 feet higher than the valley, and an easy walk to the baths.

Expenditure belongs purely to the requirements of the individual. He who finds barrenness in such grand and varied mountain ranges, clad by the mountain rose and numberless floral gems, as also by the fine clumps of the Alpine fir, must have been tutored in some unknown arcadia, where one would fear the breath of life could not be breathed as in the Upper Engadine.

Yours truly,

Argyll-street, Regent-street, August, 1880. JOHN McOSCAR, M.D.

A GIGANTIC REPTILE.

AMONG the recent additions to the Geological Department of the Museum of Natural History, Central Park, New York, are some bones of reptiles obtained from the ancient cretaceous seas of Kansas and Colorado. As an illustration, we may mention that the thigh-bone of a species of *Atlantosaurus* now exhibited is upwards of six feet in length; while to show the contrast, resting close to it, is the corresponding bone, six inches long, of the largest species of crocodile of the present time. Scientists have considered that reptiles of this class reached two hundred feet in length; but since the discovery of the *Atlantosaurus* another huge form has, according to the *Scientific American*, been found, the thigh of which measures over twelve feet in length.

M.R.C.S.—The subject is one which cannot be pursued with practical advantage further than it has been carried in works on the Skin.

Mr. J. Astle.—We have no knowledge of the medicine named.

DERMOID TUMOURS OF THE CORNEA.

To the Editor of THE LANCET.

SIR,—In answer to "Coursers's" letter, I may refer him to the fifteenth volume of the Pathological Society's Transactions, in which he will find a drawing illustrative of the eyeball of an ox, on the anterior part of which hair may be seen growing from it. The specimen is to be seen in the museum of St. Bartholomew's Hospital. It is thus described in the catalogue: "A tumour, which appeared to be composed of fat and condensed cellular tissue covered by skin, grew from the outer half of the cornea and sclerótica. The conjunctiva appeared to be lost in the integument which enveloped the tumour. Long hairs, with true bulbs, grew from the skin on the surface of the tumour." Cases of a similar nature in the human subject are to be found in the Ophthalmic Hospital Reports for 1860-61, and in the works of Mr. Wardrop and Von Ammon. I may also refer to the *Journal of Anatomy and Physiology* for October, 1879, for an interesting case of development of hair on the eyeball of a dog, recorded by Mr. G. E. Dobson.

I remain, Sir, yours obediently,

Norwich, Aug. 1880.

CHARLES WILLIAMS, F.R.C.S.

To the Editor of THE LANCET.

SIR,—Your correspondent, inquiring in THE LANCET of the 7th inst. respecting the above subject, will find a similar case, with the treatment adopted, in the *Veterinary Journal*, vol. iv., p. 245. There are three other cases of corneal dermatoma recorded in the same volume.

Yours truly,

Dartford, Aug. 17th, 1880.

W. A. EDGAR, M.R.C.V.S.

* * WE may direct attention also to an article in the July number of the *Philadelphia Medical Times*, in which is published a paper by Dr. J. B. Roberts on the above subject. Specimens of the abnormality, removed from a young bullock, were shown at the Philadelphia County Medical Society. Each cornea was partially covered by a circular, somewhat elevated growth, closely studded with reddish hairs about three-eighths of an inch long, such as are seen on the skin of oxen. In one eye the tumour involved the sclerotic region, and then invaded the cornea to about one-third, while in the other organ the growth appeared to be limited almost exclusively to the corneal tissue. The tumours were nearly the size of a ten-cent piece, and in one the continuity of the conjunctiva and the sclerotic with the surface of the growth was readily apparent.—ED. L.

Pericula.—We fear our correspondent, in the present state of the law, would not be able to recover charges for attendance during the period in which his name was erased from the Register owing to change of address.

Mr. F. B. Lee.—Anatomy: Ellis's Demonstrations; Gray or Quain. Physiology: Kirkes or Foster.

C. S.—Bischof's spongy iron filter, 505, Oxford-street.

A. K. C.—We are not aware of the facts.

THE NAVAL MEDICAL SERVICE.

To the Editor of THE LANCET.

SIR,—IN THE LANCET of August 7th, the letter of "Roderick Random" draws attention to the Admiralty again passing over their own medical officers. The writer seems not to be aware that their lordships reduced the salary one-third, from £150, as heretofore, to £100 at present, at least so far as is publicly known. The private communications about this £50 a year must have been interesting, as no information or announcement about it was made to others. This is probably the great reason (and their lordships have always a surfeit of reasons for refusing or giving); but the political and diplomatic may have influence to counteract or propitiate Dr. Nevins and his party. It is surprising that civil practitioners in any practice can accept such appointments, not alone for the peculiar duties, but the time that is consumed if the regulation time is kept, and there is not otherwise undue hurry. This and the other appointments held by civilians under the Admiralty may suggest to the youthful medico thinking of entering the Royal Navy the prudence of remaining a civilian.

August 11th, 1880.

Yours &c.,

Z.

POPULAR SANITARY LITERATURE.

THE House and Home, a publication which conveys in a popular style much useful information on matters connected with the health and comfort of households, has now, we are informed, become the recognised organ of the Working Men's Club movement. The number for August 14th contains a good portrait of Professor Huxley.

Dr. Irving is referred to page 199 of *THE LANCET* of July 31st for the answer to his previous letter. He is thanked for the extract from the *Englishman*, which, however, we had previously received from India.

Students.—1. Lionel Beale's.—2. Baker's, 244, High Holborn.

Puzzled.—We should recommend our correspondent simply to live down the false report.

Mr. W. J. Kilner.—The paper is marked for insertion.

SUPRA-PUBIC PUNCTURE OF THE BLADDER.

To the Editor of *THE LANCET*.

SIR,—With reference to Mr. Marsh's letter on the above subject in your issue of May 8th, I have much pleasure in forwarding you a few notes of a case in which I performed the operation on a native.

On Nov. 20th, 1875, when in charge of the Civil Hospital, Malligam, I was called up to see a bunya (or native merchant), who was suffering from retention of urine. The man had been very much catheterised previous to my seeing him by the native doctor. The patient was apparently about twenty-seven years old, and presented all the symptoms of retention, the bladder reaching nearly to the umbilicus. I attempted to pass a catheter, beginning with a No. 8, but failed. There being no curved trocar and cannula by which the bladder could be punctured per rectum, I punctured the bladder with a small trocar and cannula above the pubes, and drew off a very large quantity of urine, to the great relief of the man. The cannula was tied in, and a plug put into the hole to prevent the urine dribbling. I ordered him a chloral draught.

Nov. 21st.—I found the patient very well; no pain in the abdomen, but a great deal of pain complained of in the urethra; bowels opened; urine passed freely through cannula.

22nd.—The patient worse this morning; no urine passed through cannula; the abdomen was very tympanitic. A No. 8 gum-elastic catheter was passed easily into the bladder, having first of all injected some oil in the urethra. No urine appeared. Warm water was injected into the bladder, and it returned on gentle pressure over the bladder. The catheter was tied in, and the cannula over pubes removed. Turpentine stupes and cupping over the loins ordered, and aromatic spirits of ammonia three times a day. On my evening visit I found the man had a fit of ague; has passed urine several times through the catheter; tongue clean; pulse good; bowels opened. Ordered five grains of quinine every four hours.

23rd.—The patient free from fever. The catheter (which brought away a great deal of discharge) was removed, and a silver No. 8 passed; this was replaced during the day by a gum-elastic No. 8. Feels very comfortable.

24th.—Patient feels very well this morning. Removed the catheter, which was not replaced. I was called in during the evening to pass an instrument, as he could pass no urine voluntarily. I passed a No. 8 silver, and tied it in for the night.

25th.—The patient had a bad night; feels weak; bowels opened three times. I drew off about two pints of urine, removed the catheter, and did not pass another.

26th.—Patient much better; passed his urine voluntarily last night for the first time; discharge from urethra, but no pain.

27th.—Discharge slight from urethra; otherwise feels quite well; urine passes freely.

28th.—The patient left the hospital with a slight discharge from the urethra, which in a few days left him.

The man confessed to having had two or three attacks of gonorrhoea, but never any retention of urine, which I think was due to spasm of the urethra. With the exception of the symptoms of suppression of urine, which I do not think were due to the supra-pubic operation, he had hardly any bad symptom.

I should have no hesitation in performing the supra-pubic operation, in preference to the one by the rectum, if I had another case, and, as Mr. Marsh says, no preliminary incision need be required. The instrument used was the ordinary small-sized hydrocele trocar and cannula.

Your obedient servant,

JAMES S. WILKINS, M.R.C.S. Eng., &c.,
Garrison Surgeon, Fort Asirgarh, C.P.

June, 1880.

CONSULTANTS VERSUS GENERAL PRACTITIONERS.

To the Editor of *THE LANCET*.

SIR,—I sent a patient suffering with severe inflammation of the eye-ball, and whose sight was seriously imperilled thereby, to a London ophthalmic surgeon the other day for his advice. He at once told my patient that "if she had been another day under my treatment she would certainly have lost the sight of her eye." The friends of the patient thereupon wrote to me, declining to pay my charge for attendance on the case, on the ground that it had been wrongly treated. As I have never had any similar experience before, I should be glad to know if it is usual for consultants to freely express their opinions of the line of treatment previously employed to the patient or the patient's friends; and, further, whether such expression of opinion is in any case, or under any circumstances, justifiable.—Your obedient servant,

August, 1880.

A COUNTRY PRACTITIONER.

Students, (Dublin).—Mysophobia is a form of mental derangement characterised by a morbid fear of defilement or contamination. Ten cases of this affection are described by Dr. William A. Hammond in No. 1, Vol. I., of "Neurological Contributions" (New York: Putnam's Sons). The very interesting and important paper therein reprinted was read before the New York Neurological Society, April 7th, 1879.

Mr. J. H. Schorer, (Berlin).—We cannot exchange.

HOW ANTI-VACCINATION STATISTICS ARE MADE.

To the Editor of *THE LANCET*.

SIR,—I send you an extract from the *Northern Echo*, to which I wish to call your attention, and should like to have your opinion.

"ALLEGED DEATH FROM VACCINATION AT WEST HARTLEPOOL.—A coroner's inquest touching the death of an infant was held on Saturday afternoon at the Burn Hotel, Stranton. According to the mother's statement, Mr. M'Bride, Dr. Moore's assistant, attended her in her confinement, and the child was vaccinated when two months old by Dr. Moore, jun. That was upwards of twelve months ago, and the child had never been well since. Soon after undergoing vaccination the child broke out in spots all over its head and face, and it continued to get worse until it died on Friday. The child was full-grown when born, and perfectly healthy. Dr. Swanwick, who examined the body on Saturday morning, gave it as his opinion that death was due to syphilis from inoculation, as from the parents and other members of the family there was no reason to suppose it was hereditary. As that could not have been avoided, death must be set down to natural causes. He stated, in reply to a question, that he once attributed a death to vaccination; but he was undeceived when a member of the same family died before being vaccinated, the symptoms being similar. Vaccination, again, might bring out the seeds of disease previously dormant. The jury found a verdict in accordance with the medical opinion expressed by Dr. Swanwick."

1st. As to the conduct of the coroner in calling in a medical man to give evidence upon mere external examination, who had never seen the child alive, and knew nothing of the family history of the case, and in returning a verdict on such evidence. Also, why the medical man who attended the child was not called as a witness, and why the medical man who acted as deputy in place of the public vaccinator, and against whom the charge was made, was not called.

2nd. As to the evidence of the medical man examined. Is a medical man justified from external examination of a child dead some time to say whether syphilis was acquired or hereditary?

All this, taken in connexion with the said medical man's opinion in a former case of supposed syphilitic poisoning, which he had to retract, along with the present disturbed state of public opinion on compulsory vaccination.

I had nothing to do with the case, never saw the child, but know all the parties concerned.

I enclose my card, and am, Sir,
West Hartlepool, August 2nd, 1880.

Yours truly,
FAIR PLAY.

* * It is clear that no such opinion could be of any value apart from a careful inquiry into the history and a post-mortem examination, and that the evidence of the medical man who performed the vaccination should have been sought. The evidence that the vaccination had anything to do in producing the syphilis, if syphilis existed, is absolutely wanting. It is much to be regretted that medical men should lend themselves to the purposes of anti-vaccination agitators.—ED. L.

A HINT FOR VISITORS TO BRUSSELS.

To the Editor of *THE LANCET*.

SIR,—In reply to several communications which I have received from professional brethren, who propose visiting Brussels this summer on the occasion of the anniversary fêtes, will you kindly permit me to say through your columns that the latter end of this month and September is the best time for seeing the Ardennes, of which Spa is the chief town. Spa is distant from Brussels about four hours by rail, and frequent trains run daily. Comfortable board and lodging may be obtained for about fifty francs a week. To any members of the profession desirous of making acquaintance, under unusually favourable circumstances this year, with the historic district of the Ardennes and its important chalybeate springs, I shall be very glad to afford any information or assistance in my power.

Yours &c.,

LITTON FORBES, M.D.,
Resident Physician.

Spa, August, 1880.

THE MEDICAL ASPECT OF FREEDOM OF CONTRACT.

To the Editor of *THE LANCET*.

SIR,—Can any of your readers inform me, through your columns, of a case where a Judge has given judgment, or the law on the subject, where an assistant, having been bound by agreement not to practise within a certain distance of his principal, does so practise contrary to that agreement?

Sir Wm. Harcourt says in a speech on Freedom of Contract (*The Times*, June 11th, 1880): "Under common law many contracts were null and void, as, for example, contracts in restraint of industry and trade, which prevented a party obtaining a livelihood in any particular vocation or profession, were absolutely null and void, as being contrary to public policy." Does that apply to a contract between a medical man and his assistant?

Yours &c.,

ASSISTANT.

August, 1880.

TREATMENT OF BURNS.

DR. SHRADY, of New York, has recently treated burns by applying a paste composed of three ounces of gum acacia, one ounce of gum tragacanth, one pint of carbollised water (one to sixty), and two ounces of molasses. It is applied with a brush, renewed at intervals, and is stated to be a successful method. Four applications are usually sufficient, the granulating surfaces being treated with simple cerate or the oxide-of-zinc ointment, as indicated.

C. M. C. has forgotten to enclose his card. Moreover, the question he propounds is not a medical one.

Mr. W. H. Middleton.—The same sum should be paid for the wives as for members.

ERRATA.—In our report of the meeting of the British Medical Association last week, the honorary degree granted to several medical men was by a printer's error stated to be "LL.B.," it should, of course, have been "LL.D." It was "Mr. F. Jordan," and not "Gordon," who took part in the debate on Bigelow's operation. In Mr. Erichsen's speech on the treatment of wounds, in the 2nd line, "Lister" is printed for "Liston"; and in line 10, "antiseptics" should read "anesthetics." In several places Mr. Cheyne's name was wrongly printed "Chiene."—In the list, published in our last issue, of the medical officers serving in Afghanistan, in the first division of the Northern field force, the name of the surgeon in charge of the 68 R.A. should have been printed E. H. Fenn (formerly house-surgeon at the Middlesex Hospital), and not "Févre."—The name of the coroner for the Eastern Division of Middlesex was printed wrongly in our annotation on page 226. It should have been Humphreys, not "Humphrey."

COMMUNICATIONS, LETTERS, &c., have been received from—Mr. C. Lucas, London; Mr. J. Hutchinson, London; Mr. L. Tait, Birmingham; Dr. Sturges, Lafford; Mr. Mardon, Littlehampton; Mr. Lee, Heckmondwike; Mr. Rearden; Mr. J. Taylor, Cleland, N.Z.; Mr. Edgar, Dartford; Dr. Walker, Crick; Mr. Evans; Dr. L. Forbes; Mr. Maples, London; Dr. F. W. Smith, Leamington; Dr. Budd, jun., Clifton; Dr. MacLagan, London; Mr. Broom, Wolverhampton; Mr. Sandys, Cambridge; Captain Hobson, London; Mr. J. T. Jones, Barnstable; Dr. Milson, London; Mr. Wolfenden; Dr. Fenn; Mr. M. Rosenblad, Kalmar; Dr. Ranking, Dublin; Mr. Meredith, London; Dr. Gairdner, London; Dr. Sim; Mr. Middleton, Williton; Mr. Garnell; Dr. Wallace, Greenock; Dr. Coombe, Twyford; Mr. Groves, Brixton; Mr. Callant, Bridgnorth; Mr. Maycock, Leamington; Mr. Kemp, London; Dr. D. The above Scale of Charges is arranged upon the basis of the classification adopted in the Index.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements (on page 2), which not only affords a ready means of finding any notice, but is in itself an additional advertisement.

Advertisements (to ensure insertion the same week) should be forwarded at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed.

Advertisements are now received at all Messrs. W. H. Smith and Sons' Railway Bookstalls throughout the United Kingdom.

The postal arrangements relating to the distribution of THE LANCET will be considered from time to time in the interests of subscribers.

Tables of Contents, with the Index of Advertisements, for each Number can be had on application to the Publisher.

Agent for the Advertising Department in France—J. ASTIER, 67, Rue Caumartin, Paris.

Lectures

ON THE

PHYSICAL EXAMINATION OF THE MOUTH AND THROAT.

Delivered to the Junior Class of Clinical Medicine, University College,

By G. V. POORE, M.D., F.R.C.P.,

PROFESSOR OF MEDICAL JURISPRUDENCE, UNIVERSITY COLLEGE; LATE ASSISTANT PROFESSOR OF CLINICAL MEDICINE; ASSISTANT PHYSICIAN, AND PHYSICIAN IN CHARGE OF THE THROAT DEPARTMENT OF THE HOSPITAL, ETC.

LECTURE V.

LARYNGEAL PARALYSES: ALTERATIONS IN PHONATION AND ARTICULATION.

GENTLEMEN,—The larynx is the seat of many forms of paralysis, and we often see an impairment in the movements of the vocal cords owing to failure of one or more of the muscles which move them.

It may be well to recall your minds for a few moments to the muscles of the larynx. One may begin by saying that the mucous membrane of the larynx, except at the margins of the true vocal cords, everywhere immediately covers muscular fibres, which fibres have been grouped and named by anatomists. The best marked of these groups are—

1. The posterior crico-arytenoid muscles, which arise from the impressions on the posterior surface of the cricoid cartilages, and are inserted into the outer angle of the base of the arytenoid cartilages. These muscles rotate the arytenoid cartilages *outwards*, and thus cause the *processus vocales* to diverge. They cause the vocal cords to separate widely, or, in other words, they *abduct* them. These are the only muscles which separate the cords.

2. The crico-thyroid, a triangular muscle passing obliquely upwards and outwards from the front of the cricoid cartilage to the lower border of the thyroid cartilage, causes the thyroid to move downwards and forwards over the cricoid, and thus produces tension of the vocal cords.

3. The arytenoid muscle passes from one arytenoid cartilage to another, and causes them to approximate, and hence helps to close the glottis.

4. The lateral crico-arytenoids pass from the upper margin of the cricoid to the outer angle of the arytenoids, and cause the arytenoid cartilages to rotate inwards. These muscles are *adductors*, antagonists of the posterior crico-arytenoids, and help to close the glottis.

5. The thyro-arytenoid muscles run parallel to the vocal cords from the thyroid to the arytenoid cartilages, and tend to relax the vocal cords.

6. The muscular fibres covered by the aryteno-epiglottic folds of mucous membrane help to close the glottis and depress the epiglottis, and the thyro-epiglottic muscle also tends to depress the epiglottis.

These muscles are all supplied by branches of the vagus, the crico-thyroid by the superior laryngeal, and all the others by the recurrent laryngeal. Now, since the great cause of paralysis is a lesion involving the origin or trunk of a nerve supplying a muscle, it is necessary in considering the paralyzes of the larynx to bear in mind the origin and course of the vagus and its laryngeal branches.

The vagi having their deep origins in a grey nucleus at the lower part of the floor of the fourth ventricle, start from the lateral tract of the medulla, and, being joined by fibres from the glosso-pharyngeal and spinal accessory, pass through the jugular foramen, and down the neck within the sheath of the carotid vessels lying between the internal jugular vein and the internal and common carotid arteries as far as the root of the neck. The right nerve crosses the subclavian artery between it and the subclavian vein, while the left, lying between the left carotid and subclavian arteries and behind the left innominate vein, crosses in front of the arch of the aorta. The right recurrent laryngeal nerve arises in front of the subclavian artery, winds from before back around the subclavian, and ascends obliquely to

the side of the trachea behind the common carotid and inferior thyroid arteries. The left recurrent laryngeal nerve arises in front of the arch of the aorta, and winds from before back around the aorta, close to the junction of the transverse and descending portions of the arch, and just beyond the junction with it of the obliterated ductus arteriosus, and then ascends to the side of the trachea. Both nerves ascend in the groove between the trachea and oesophagus, and enter the larynx behind the articulation of the inferior cornu of the thyroid cartilage with the cricoid. It is a matter of great clinical importance to bear in mind how the course of the vagi in the neighbourhood of the origin of the recurrent laryngeal nerve differs on the two sides. The left recurrent has its origin, so to say, much deeper in the thoracic cavity than the right, and encircles the aorta just beyond the main branches of the arch. This part of the aorta lying deeply is not, as it were, very accessible to direct clinical observation; but by the fact that disease of this part often causes injury to the left recurrent laryngeal nerve we are often enabled from the impaired functions of this nerve to infer disease in the neighbourhood of the junction of the transverse and descending parts of the arch of the aorta. Once more reminding you that disease, injury, or pressure upon the recurrent branches of the vagus, or of the trunk of the nerve superior to their origins will cause paralysis of the laryngeal muscles, we will consider the appearances produced by these paralyzes.

In a normal larynx the vocal cords are of a pearly whiteness, and appear of an equal width on either side (about one-eighth of an inch). The chink between them runs directly in the middle line. During deep inspiration the cords separate widely, the tips of the arytenoid cartilages recede from each other, and the aperture of the glottis assumes a somewhat lozenge-shape, like an ace of diamonds truncated at its lower end.

During phonation (as when we ask the patient to say "Ah") the cords approach each other, and almost meet in the middle line, and the tips of the arytenoid cartilages approach each other so as to be almost in contact. If we ask a patient alternately to take a deep breath and say "Ah," we see how vigorous the movement of the vocal cords is in health. If the patient can sing, and we ask him to ascend the scale, we see, as the note gets higher, the chink between the cords get narrower, but in a degree which is scarcely perceptible. During the utterance of very high falsetto notes the *processus vocales* of the cords are seen to touch each other, and the chink between the anterior part of the cords gets wider.

I will here remind you that failure of movement of the cords may be produced by causes other than nerve injury, such as—(1) Mere muscular weakness, as in anæmic conditions and emotional causes; (2) functional nerve troubles, as in hysteria and some forms of stammering; (3) direct injury to the muscles by inflammation above or beneath them, and consequent impairment of their nutrition; (4) disease of the crico-arytenoid articulations; (5) mechanical impediments to free movements, such as swelling of the mucous membrane, or the presence of polypi or warts, or, as I have actually seen, one cord may be glued in one position by the tenacious *mucopus* covering the mucous membrane.

The cords on either side may be unequally exposed. This may be due to a swelling of one false cord preventing a full view of the true cord beneath; or it may be caused by a loss of the power to adduct the cord which is least exposed, or to abduct the cord which is most exposed. When the cords are unequally exposed, and the glottic chink runs obliquely instead of directly in the middle line, we may be sure there is failure of movement on one side or the other. On asking the patient to say "Ah," we may notice that there is a *failure more or less complete to approximate the cords*. They may remain motionless, with the glottic aperture open nearly to the full, or the cords may make an attempt to approach in a tremulous, hesitating manner. This is due to muscular weakness in the adductor muscles, and is almost always brought about by anæmia. It is very common in hysterical women, but also occurs in males. The most marked case I have seen was in a boy after one of the acute specifics, whose larynx showed an extreme degree of anæmia. Cure the anæmia and the trouble gets well.

One vocal cord may be seen to move vigorously while the other remains stationary. This is the most common and the most important of the laryngeal palsies, because it indicates, in the majority of cases, disease or injury of the recurrent laryngeal nerve on the side of the immovable cord. It often happens that phonation is normal in these cases, because the

healthy cord when adducted overpasses the middle line, and comes into nearly perfect contact with its fellow. This palsy is far commoner on the left side than the right, and is then generally due to an aneurism of the transverse part of the arch of the aorta. So often is this the case that it should be a rule of practice, whenever the palsy is seen, to make diligent search for aortic aneurism. In every case of obscure chest symptoms, with deep-seated, shooting pains, &c., the larynx should always be examined, to ascertain if there be any failure of action of one cord. This should be a matter of routine never to be departed from, for the inaction of the cord may precede every other symptom, and may occur without there being either hoarseness or cough to direct attention to the larynx. If I were asked to name the chief service which the laryngoscope had rendered to medicine, I should unhesitatingly reply that it was the facility it had given us for the diagnosis of the early stages of aortic aneurism. I need not say that pressure upon the vagus in its recurrent branch by tumours of any kind or by disease of the nerve will cause the paralysis. Aneurism, however, remains the cause *par excellence*.

We occasionally see a *paralysis of the abductors* of the vocal cords due to a failure of contraction in the crico-arytenoidei postici muscles. With the laryngoscope we see that when the patient takes a deep breath (or rather attempts to do so, for very full inspirations are not possible in this condition) the vocal cords do not separate as they do in health, although when he expires forcibly the glottic clink may be somewhat widened by the forcible separation of the cords by the outgoing blast. During attempts at phonation the approximation of the cords is perfect, and the voice is normal. If this form of paralysis persists, the adductors not being antagonised, the cords gradually approach each other, so that the patient's life is endangered owing to the difficulty in drawing air through the closed glottis. It is caused by a failure of one group of muscles, and is more often due to local trouble, such as necrosis of the cricoid cartilage, and consequent involvement of the neighbouring muscles in the inflammatory process, than to nerve lesions. It sometimes appears to be "functional," and has also been seen complicating chronic nervous diseases, such as locomotor ataxia.

Besides these common and well-established forms of laryngeal paralysis, there are others which are less common. A *paralysis of the crico-thyroid muscle*, the tensor of the cords, has been described; and it is alleged that the border of the cords appears wavy and slack. I have seen a wavy condition of the cords, but have regarded it as being caused by chronic catarrh and impairment of the elasticity of the cord. The crico-thyroid being supplied by the superior laryngeal nerve, the sensory nerve of the larynx, one would look for evidence of impairment of sensation in these cases.

A *paralysis of the arytenoideus* and a consequent failure of the arytenoid cartilages to approximate during phonation have been described.

Before leaving the subject of laryngeal paralyses, I will enumerate some of the chief causes of the *nerve lesions* to which they are due. These are—

1. Central lesions, such as: (a) Bulbar paralysis, (b) locomotor ataxia, (c) Cruveilhier's atrophy (?). It is not often that the laryngeal symptoms are very marked in these conditions, and the laryngoscope is generally required to make out the want of activity in the laryngeal muscles.
2. In some rare cases of lead palsy there have been laryngeal paralyses.
3. In "diphtherial" paralysis.
4. Pressure on the trunk of the vagus in the neck by tumours of any kind.
5. Pressure upon or stretching of the recurrent laryngeal nerves by (a) aneurisms; (b) mediastinal tumours; (c) pleuritic thickenings about the apices of the lungs; (d) growths involving the œsophagus and implicating the recurrent laryngeal; (e) any tumours of the neck.

With regard to spasms of the larynx, these are more a matter of inference than direct observation; and I shall reserve the discussion of them till a later period.

We have now finished the *inspection* of the mouth and larynx, and we may proceed to consider the *auscultation* of these parts. In auscultation the stethoscope is of little or no use, and the facts to which I wish to draw your attention are the various sounds emitted by the vocal apparatus as they strike our unaided ear.

First, as to derangements of speech. In speech there are two factors—viz., *phonation* and *articulation*: the production of the sound and the moulding of the sound into words. Either or both of these functions may be deranged.

Phonation is the work of the larynx. It is caused by the

vibration of the vocal "reeds" (misnamed "cords") set in motion by a blast of air driven past them, just as the "reed" or lamella of a concertina is set vibrating by the bellows. Now for the production of a normal tone with the larynx it is necessary: (1) that the cords should be of their normal texture and thickness so as to vibrate easily; (2) that they should be brought almost into complete contact with each other so that the merest chink only exists between them; (3) that the normal tension of the cords should be maintained; (4) that the blast of air driven between them should be sufficient to cause a full vibration. Now if any of these four factors of phonation be at fault, we get a deficiency or an alteration of the normal tone of the voice, and the patient is either *aphonic* or *hoarse*.

In *aphonia* the voice may be reduced to a scarcely audible whisper, and it is caused either by a failure of the vocal cords to approximate, as in hysterical or anæmic aphonia, or by a failure of the proper blast of air, as in conditions of great exhaustion. In hysterical aphonia you will observe that the patient makes no great effort to emit a sound. The lips move, but no sound issues from them. The absence of effort on the part of a patient otherwise in tolerable health is almost sufficient for the diagnosis of the cause of aphonia. Aphonia may be produced by emotional causes, and the phrase "struck dumb with emotion" is common enough in newspapers and works of fiction. Aphonia—i.e., absence of phonation without alteration of quality—is a rare condition. *Hoarseness*, on the other hand, is met with every day, and is the commonest of all symptoms of laryngeal disease. It may arise from very different conditions; whenever it is present the laryngoscope should be used as a matter of routine, and it may be said that the chief use of the laryngoscope is to determine the cause of hoarseness. Hoarseness is of two kinds. It may be complete, as when the voice is reduced to one prolonged stridulous whisper; or the voice may be mainly hoarse, but bursts into tone as it were for short, transient moments. This latter variety I have called *mixed hoarseness*. When present it always indicates that the cause of the hoarseness is such as can be overcome by effort, or is movable.

Alteration in the texture of the cords is a common cause of hoarseness. Mere hyperæmia, or the slight thickening caused by catarrh, or the greater amount of thickening produced by chronic inflammation or syphilitic infiltration prevents the proper vibration of the cords and produces hoarseness. The accumulation of tenacious mucoid secretion upon the cords and between them prevents this vibration and interferes with the blast of air, produces hoarseness, and adds to the voice other vibrations, which are not vocal. In laryngeal catarrh due to any cause this condition exists, and the hoarseness is often "mixed" as I have called it, because when the mucus is removed either by a cough or a laryngeal brush, the voice becomes normal until the secretion reaccumulates. Brushing out the larynx with various astringent solutions has been commonly practised in chronic laryngitis, whether of a simple, tuberculous, or syphilitic nature. You have often seen patients come into the throat department absolutely hoarse; you have seen me take a brush dipped in an astringent solution, and pass it down to the vocal cords, the brush returns with a lump of mucus adhering to it, and the patient probably has a violent fit of coughing and expectorates another lump. By this means an obstruction to the proper vibration of the cords is removed, and the patient, whose voice becomes normal, or almost normal, conceives a great veneration for laryngeal mirrors and curved brushes, and looks in wonderment at the lump of mucus which has been removed. Of course, in chronic cases the hoarseness returns in a few hours, and possibly the passage of the brush may have rather intensified the causes of the catarrh. There is no doubt that the laryngeal brush has been much over-used, and I would here warn you that the over-use of an instrument is liable, especially in private practice, to bring the operator and his art into disrepute.

The cords may fail to approximate from various causes, the chief of which is muscular weakness and paralysis. When the cords fail to meet the patient tries to produce a sound by increasing the force of the blast of air from his lungs, and the result is hoarseness. We lately had a boy in the out-patient room who had been suffering from hoarseness, and whose condition, diagnosed elsewhere as laryngitis, had been treated by the application of counter-irritants and the administration of so-called "antiphlogistics." The laryngoscope showed great anæmia of the larynx, and proved that the cause of his hoarseness was a failure in the

power of the adductors. Fresh air, good food, and iron soon removed his trouble.

When one cord alone is paralysed there is generally hoarseness at first, and there is always occasional hoarseness. It is remarkable to find how hoarseness disappears in these cases after a time. The reason, however, is plain. It is, that the healthy cord, which at first fails to come into apposition with its fellow cord, does so easily later on, because in adduction it over-passes the middle line of the larynx and touches its paralysed fellow. It may be also that the tension of the paralysed cord gradually improves, owing to the fact that the crico-thyroid muscle (supplied by the superior laryngeal nerve) is unopposed by its antagonist (supplied by the paralysed recurrent laryngeal nerve).

The proper approximation of the vocal cords may be prevented by growths, whether simple or malignant, arising from them or projecting between them. This is a condition at once made clear by employing the laryngoscope. One often sees an hypertrophied, and, perhaps, ulcerated fold of mucous membrane in the inter-arytenoid space projecting between the cords and preventing their free movement. Swelling of the false cords may be so great as to prevent the approximation of the cords.

The normal tension of the cords may not be maintained, or the tension of one cord may not be maintained, and thus we get hoarseness more or less complete. I have seen one instance, and only one, in a case which I saw in consultation with Mr. Tweed, in which the cord presented a wavy edge instead of a straight one during phonation, and the voice had a certain husky, tremulous, bleating quality, which was very characteristic. Whether this want of tension in one cord was produced by want of power in the crico-thyroid or by chronic catarrh I could not determine.

If the voice be very much used, and especially if it be very much used in foul atmospheres, such as are usually found in ill-ventilated theatres, churches, concert-rooms, and drawing-rooms, the muscles which move the cords, and especially the tensors, become tired and the musical quality of the voice gives place to hoarseness or huskiness. This is first observable during the emission of high notes, because the proper high degree of tension of the cords is not maintained. This form of singer's hoarseness is brought about by fatigue of the vocalising muscles, and it is important to remember that this fatigue is most easily produced in over-heated, foul, enervating atmospheres, and it is not surprising that fine tenor singers shrink from committing vocal suicide in the wretched rooms in which they are often expected to sing.

Failure of the proper blast of air may be caused by obstruction below the cords, as by tumours pressing on the trachea, or cicatricial contraction of the larynx or trachea. In cases of wound of the trachea, in which nearly all the expired air escapes by the wound, the consequent aphonia may be almost absolute. In conditions of great weakness the blast may be deficient in force, and in cases of extreme emphysema there is always an impairment of the quality of the voice.

Phonation may be fairly good, but the patient may be nearly or quite incapable of altering the pitch of his voice. This shows want of muscular power. It is present in cases of labio-glosso-laryngeal paralysis, where both the cords are paralysed. It was present also to a marked extent in a patient whose case was recorded by Dr. Yeo and Mr. Lister. This patient's vocal cords were completely removed by the operation of thyrotomy, but notwithstanding this fact, he managed, after his recovery, to speak fairly well in a low-pitched monotone. By the kindness of Dr. Yeo I examined the patient's larynx, and it was most interesting to observe how phonation was produced by an approximation of the aryteno-epiglottic folds. It is generally taught that the vocal cords are essential for phonation, but this case proved how completely their functions might be assumed by other parts.

I have shown sufficiently how the symptom "hoarseness" may depend upon many different pathological conditions, and I will now pass on to consider alterations in the second factor of vocalisation—viz., "articulation."

Articulation is brought about by muscular movements of the jaws, lips, cheeks, tongue, and soft palate. At the onset of this subject one may remark that articulation may be performed in many ways, and after removal of parts which we might consider essential the patient will accommodate himself to circumstances in a remarkable way. Thus it is well established that people can talk almost perfectly without a tongue. In the same way unilateral paralysis of

the muscles of articulation has wonderfully little effect after the lapse of a short time, and the loss of the teeth is soon compensated for. On the whole, defects of articulation are not of such clinical importance as to warrant one in spending much time upon the subject, and I will merely indicate some of the more important points, and refer those who want more information to Dr. Bristowe's excellent lectures on the subject, delivered last year at the College of Physicians.

The vowel sounds (pronounced in the French manner) *a, é, i, o, u*, depend upon the relative size of the oral opening and the oral canal. Thus "a" requires the mouth wide open, while "u" necessitates an extreme contraction of the orbicularis oris. The sound "aw," as in "hawk," necessitates a contraction of the pharynx.

Certain consonants demand a large amount of lip contraction—such as "p" and "b." Others demand vigorous movements of the tongue—such as the vibratile "r," in which the tip of the tongue is set vibrating; "t" and "d," in which the tip of the tongue is brought forcibly against the teeth, and also "ss" and "th," in which the tip is protruded between the teeth. Lastly, the hard "g" and "k" demand a considerable amount of pharyngeal contraction.

A knowledge of these facts enables us to employ test words for the detection and localisation of the seat of defect in articulating power. Thus the words "Pooh! pooh!"—or, better still, "Booby"—will serve to test the lip power, as they involve the utterance of a labial consonant and the labial vowel sound. Such a word as "thrill" will especially test the tongue power, and "hawk," or "gawk," will test the power of pharyngeal contractions.

In no condition is the power of articulation so completely lost as in bulbar paralysis or labio-glosso-laryngeal paralysis. Here lips, tongue, palate, and larynx are all affected, and the patient is reduced to the utterance of monotonous inarticulate sounds. Unilateral paralyses or atrophies interfere singularly little with articulation. A sore place upon the tongue effectually stops the utterance of such words as "thrill," "tittle, tattle," &c.; but we have lately had a girl attending the out-patient room who could say all these words perfectly, in spite of very marked atrophy of the right side of the tongue. The loss of the front incisor teeth while the lateral remain puts an end to the proper utterance of "F's" and "V's," although the patient soon learns, unconsciously, to compensate for this as for every other defect. When all the teeth are lost the rim of the gums takes their place, and articulation becomes perfect again.

The presence or absence of nasal resonance is a point worthy of attention, and one capable of affording a considerable amount of valuable information. The nasal cavity, as you are aware, is shut off from the oral cavity by the pressure of the soft palate against the pharynx during the utterance of all sounds, except those of "m," "n," and "ng."

The labial sound "b," as in "bab," the dental sound "d," as in "dad," and the palatal sound "g" (hard), as in "gag," which are all normally produced with the nasal cavity shut off, become altered to the naso-labial sound "mam," the naso-dental sound "nan," and the naso-palatal sound "ngang," when the nasal is not shut off from the oral cavity. Salter gives the following as a sample of this kind of utterance, the words "Both brothers drove in a gig" becoming "Moth mrothers nrove in a nging." Now, whenever we hear this kind of utterance, we may be sure that there is a difficulty in shutting off the nasal cavity, and we shall expect to find: (1) a cleft palate, (2) a perforation of the hard or soft palate, (3) a paralysis of the soft palate, or (4) a mechanical obstacle to the movement of the soft palate.

It is common to find the reverse of what we have been describing, and to hear sounds which should be nasal uttered without their nasal quality. In this case "m" becomes "b," "n" becomes "d," and "ng" becomes (hard) "g," and (again to borrow a sample from Salter) the sentence, "The afternoon was fine, though the morning was rainy," becomes "The after-dood was fide, though the bordig was raidy." This is the well-known pronunciation of the sufferer from a common cold, owing to the swelling of the nasal mucous membrane and the impossibility of driving air through the nasal cavity. Whenever we hear this pronunciation we may be sure that the nose is shut off from the mouth by: (1) a common cold; (2) by the adhesion of the soft palate to the pharynx; (3) by the presence of nasal polypi or other tumours; (4) by post-pharyngeal abscess. The lesson to be learnt from these facts is that whenever we have excess or deficiency of nasal resonance we should at once search for the cause.

Lectures

ON

THE RELATIONS OF SARCOMA TO CARCINOMA.

Delivered at the Royal College of Surgeons in June, 1880,

By HENRY TRENTHAM BUTLIN, F.R.C.S.,

ERASMUS WILSON PROFESSOR OF PATHOLOGY TO THE COLLEGE,
ASSISTANT-SURGEON TO ST. BARTHOLOMEW'S HOSPITAL, &c.

LECTURE I.—PART II.

TUMOURS OF THE TESTIS.

If in many points the foregoing cases differ widely from one another, there are yet some points common to all. And if a larger number of cases of sarcoma and carcinoma be compared, I think it will be found that the characters which they possess in common are more numerous than those by which they are distinguished. For example, the conditions of occupation and social position, of marriage, of previous health and family history, appear to exercise no greater influence on the production of one than of the other disease. The histories of both diseases are the same with regard to cause, rapidity of growth, pain, and previous inflammation. In shape, contour, and consistence their characters are very similar, except that sarcoma is sometimes very hard. Nor is the relation of the tumour to the scrotum or the condition of the cord helpful in diagnosis. Even after removal it is often impossible to distinguish between sarcoma and carcinoma unless the microscope be employed, for the position of the growth may be the same in either case. Each may contain cysts, each may exhibit an encephaloid appearance; and, although the presence of cartilage proves, as I believe, that the tumour is a sarcoma, the absence of cartilage does not prove it to be a carcinoma. Regarding the characters in which they differ, again I think it will be found that the cases of sarcoma differ more markedly from one another than do the cases of sarcoma from those of carcinoma. Unfortunately, I have not an equal number of cases of each disease to compare together; and, still more unfortunately, a large proportion of the few cases of carcinoma here collected is incomplete. Of these sixteen cases, although eight are known to have died, complete autopsies were performed only in three, and a partial section in one. Again, the total duration of disease in some of the eight patients who died is uncertain, for two died from the effects of the operation of castration, and the duration of another case up to the time of operation is unknown. Yet it is possible to ascertain some important points, which I now may shortly indicate. There is only one under twenty years of age—a child of two years, whose testis was removed after it had been enlarged three months. Sections of the tumour presented so marked an alveolar structure that I believed it to be a carcinoma. Nearly two years later the patient died, as it appeared, from caries of the spine, of which many of the signs were present. But there was no abscess; and no post-mortem examination was permitted. The case is described by Mr. Marsh, and its minute characters are figured in the Transactions of the Pathological Society.¹ Although after twenty years no age was free from its occurrence, carcinoma of the testis was most frequent between the ages of thirty and forty or thirty and forty-five. It never affected more than one testis. The tumour was unmixt with other tissues. Affection of the glands was found in every case in which the abdomen was opened, and was strongly suspected in another patient, whose case I have already more fully mentioned. In two of the three complete autopsies the lungs and liver were the seat of secondary growths; in the remaining case these organs were exempt, while the suprarenal capsule was diseased.

The cases of sarcoma are twenty-eight in number. Most of them are round-celled, only three such as can be classed with neither of the first two groups. Of these twenty-eight

cases seventeen died, and on these seventeen subjects eleven post-mortems were performed, while in one case the abdomen only was examined. The disease was most frequent at two periods of life: the first period extending from birth to ten years old; the second corresponding with the period during which we have just found that men are most liable to carcinoma. I do not pretend to explain why both classes of tumour occurred so frequently during the third decade of life, a time during which inflammations of the substance of the testis are perhaps less frequent. But I imagine before the age of ten two causes concur to render carcinoma rare: first, the little liability to cancerous degeneration of epithelium of any part at so early an age; second, the inactive condition of the epithelium of the testis before the age of puberty. Both testes were occasionally affected by sarcoma. Many of the tumours were mixed with cartilage or other tissues. The glands were not diseased in every case in which examination was made, but were enlarged and sarcomatous in nine of the twelve cases in which the abdomen was opened, and the supposition of their enlargement was so strong in two other cases as to amount almost to certainty. Secondary growths occurred in the lungs in more than half the cases; in the liver only in a single case. The bones or skin, or both, were affected in five instances.

If now, instead of thus comparing all the cases of sarcoma with those of carcinoma, we compare separately the round-celled and the spindle-celled tumours with the carcinomas the results are more striking. The round-celled tumours occurred in persons of any age between eight months and sixty-four years, but most often before the age of ten or between fifty and sixty years. Both testes were not infrequently affected. None of the tumours contained cartilage or any organised tissue other than fibrous. Glandular affection was absent in two of the six cases in which autopsies were performed, and the lungs were the seat of secondary growths only in a single instance, yet in five cases there was wide-spread generalisation in the bones and skin or subcutaneous tissue. And with the skin the liver was in one patient affected. Several of these round-celled tumours, especially in those cases in which both testes were affected and generalisation was extensive, were examples of what has been called lympho-sarcoma or lymphadenoma of the testes, chiefly on account of the delicate reticulum, which can be discerned amid the cells.

The subjects of the spindle-celled sarcomas were from ten months to forty-five years old, but the disease was far most frequent in persons under ten and from thirty-five to forty-five. In no case were both testes affected. Cartilage was present in greater or less quantity in more than half the cases. The total duration of disease was rather longer in patients with spindle- than in those with round-celled sarcoma. Several of the former lived three years, most of the latter only two. Affection of the glands occurred in every case in which the body was examined after death, and in two cases in which no examination could be made, a like affection was indicated by the presence of a large tumour in the pelvis and abdomen. The lungs contained secondary growths in every case but one, and in that case a large tumour occupied the situation of the kidney. In no instance was there extensive generalisation similar to that occurring in the fatal cases of round-celled tumours.

A careful summing-up of the chief differences existing between carcinoma and sarcoma of the testis and between the varieties of sarcoma shows that, apart from those of structure and of age of occurrence, they are for the most part differences in the manner of their generalisation. Whether these differences of generalisation are due merely to modifications of structure or to some other cause I cannot now determine, if indeed I am ever able to do so. But I think I can offer an explanation of one seeming anomaly—namely, of the departure in certain cases from the general rule that the lymphatic glands are affected in both diseases. The very fact of secondary enlargement of the glands in sarcoma of the testis is contrary to the general law laid down in many text-books teaching that sarcoma does not produce affection of the lymphatic glands. But if this law be true of sarcoma generally—a point to which attention will be particularly directed in the study of tumours of other tissues and organs—it is so thoroughly reversed in the present instance that we are even obliged to seek some explanation of those cases in which affection of the glands was absent. They are three in number,² two round-celled, one mixed, and they present one

¹ Vol. xxvi., p. 138.

² Nos. 5, 13, 23.

feature in common in which they differ from all the other fatal cases—their extremely short duration. The whole course of the disease in two of them was hardly longer than two months, and of the third was only five months. Castration was not performed on either of the two patients whose disease pursued the most rapid course, therefore the exception to the rule cannot be traced to operation. The only other case in which the total duration was less than a year was that of a child four years of age, who died about seven months after the first appearance of the primary tumour, and in whom the lumbar glands were sarcomatous and much

enlarged. But the duration of this case, short as it is, is half as long again as the duration of the longest of the other three, and three times as long as that of either of the two shortest. The inference is inevitable that these three patients died ere sufficient time had elapsed for affection of the glands to be developed, and that had they lived a few months longer each of them would have been the subject of glandular affection. I have already spoken of the slow progress of glandular disease, in reference to the boy under Mr. Lant Smith's care, and the same case may serve to illustrate its sometimes tardy onset.

* Death from causes connected with operation.

In connexion with the frequent combination of cartilage with spindle-celled tumours, let me try and rescue a group of tumours, which I believe to be quite innocent, from an opprobrium which most unjustly rests upon them. I mean the cartilaginous tumours of the testis. A pure cartilaginous tumour growing from bone, or indeed from such soft parts as the parotid is generally regarded, and with justice, as a quite innocent tumour. But some cartilaginous tumours, of the testis especially, have pursued a course so unexpected and so decidedly malignant that at the present time we look with suspicion upon all cartilaginous tumours of the testis, and feel that we best consult the interests of our art and our individual credit by refusing any but the most qualified opinion regarding the future of the subjects of such tumours. One of the best and most complete

cases of malignant enchondroma of the testis is that related by Sir James Paget in the Medico-Chirurgical Transactions for 1855. Studied alone it appears incontrovertible that this case was one of pure cartilaginous tumour running a rapidly malignant course, and at the period of its publication I can scarce perceive how any other explanation of it could be given. But studied as one of a group the members of which form a series of gradations between the hard and soft tumours its pathology becomes more evident. I will not recount the case in full, but may recall its salient features that the proof of my argument may be rendered more complete. The patient was thirty-seven years of age. In January, 1855, his testis was removed on account of an enlargement which had been noticed about two years. At the time of the operation thickening of the spermatic cord was

found to extend nearly to the internal ring. The tumour consisted of two main masses one above the other, and of small growths lying in the inguinal canal. The main masses were composed of nodules, tortuous, cylindrical, and knotted pieces of cartilage, embedded in a tough filamentous white connective tissue, and in the upper swellings were many thin-walled cysts, containing clear pellucid fluid. New growth could easily be distinguished in the lymphatics of the cord. Examined with the microscope the cartilage proved to be hyaline, the opaque white and softer structures showed generally a filamentous and nucleated substance and two chief structures were found in all. The axes of the connecting threads and the central substance of the growths which they supported were composed of densely nucleated substance; their exterior of a filamentous substance composed of fusiform and thin caudate corpuscles laid parallel with one another. On the 1st of May, 1855, the patient died. Lymphatics filled with new growth were traced along the course of the spermatic vessels to a large gland containing a cystic cavity lying beside the inferior vena cava. From this gland the lymphatics passed up close beside the vein, and at one point the vein was penetrated by an outgrowth proceeding from the lymphatic vessels. Both lungs were full of large cartilaginous tumours, growths of which were discovered on the inner coat of many branches of the pulmonary artery.

M. Dauvé relates a somewhat similar case in his monograph on enchondroma of the testicle.³ A man, twenty-six years old, noticed a small hard tumour at the lower part of the right testis in June, 1859. This tumour, or the testis, slowly increased in size, until in March, 1861, it measured eight by eleven centimetres, was enormously heavy, exceedingly hard, and uniformly ovoid. Castration was performed, when the testis was found to be transformed into a large tumour composed of cartilage. As in the last case so in this, the cartilage presented numerous nodules and tubes or cylinders of pearly aspect, resembling in their form and disposition the tubules of the testis. In the lower part of the tumour there was less cartilage, more fibrous tissue; and this also was the case in the epididymis, enlarged like the body of the testis. Here and there in the cord were masses of grey soft tissue made up of fibrous elements. A few days after the operation a fungous growth appeared from the stump of the cord. Later the left lower extremity began to swell, and on June 18th, about three months after the operation, the patient died. On examination after death the pelvic and lumbar glands were enlarged, soft, and grey in colour. A large suppurating tumour existed in connexion with the left kidney, but the other viscera of the abdomen, and those of the thorax, were healthy. These secondary tumours of the abdomen contained no cartilage which could be detected with the unaided sight, but with the microscope small portions were discovered. Further than this no account of the minute structure of these tumours is recorded, for the autopsy was delayed during the hottest days of a brilliant summer, and decomposition was already far advanced.

With these two cases a third may be included to complete the series. A groom, thirty-five years of age, was castrated by Mr. De Morgan for the removal of a tumour of the right testis.⁴ The growth dated from a squeeze the testis had sustained against the pommel of his saddle eight months previously. Great swelling and ecchymosis followed the injury, which subsided in two months, but left the testicle enlarged and hard. At the period at which it was removed it formed an elastic, nearly globular swelling, $5\frac{1}{2}$ inches in its long diameter. It contained numerous cysts, varying in size from a small pea to a walnut, most of which contained liquid, but some were occupied by solid growths. They were lined with epithelium, and their walls were composed mainly of connective tissue, but in the connective tissue were scattered small deposits of cartilage. The cord was not thickened; and although the tumour was of rapid growth, and the mingling of tissues was of doubtful import, it was hoped the disease was not malignant. For a year the patient remained quite well, but from that time his health began to fail, and more than two years after the operation he died. The cord was still healthy, but a large cystic mass occupied the right iliac fossa and lower part of the abdomen. Both lungs contained scattered cystic tumours, with nodules of cartilage in their substance; and the pleuræ were studded with firm pink-white masses of small size. Singularly enough, the secondary growths both of the pelvis and of the lungs con-

tained more cartilage than the primary tumour; but their soft parts consisted almost entirely of spindle cells.

The first and second of these cases are such as would generally be termed enchondroma of the testis; but if the third case had not been so described in the Transactions of the Pathological Society, it certainly would not have occurred to me to consider it a cartilaginous tumour. Since, however, it has been thus described, I am content so far to admit its claim as to group it, for the purpose of illustration, with the two more characteristic tumours; for I believe all these tumours are essentially of a like nature, and should be referred to the same class or group.

When a tumour—a carcinoma for example—becomes changed at various points into a fatty or cheesy substance, we regard this substance, and probably with justice, as the result of fatty or caseous degeneration of the tissues of the tumour. And even when it occurs so largely as to affect the moiety or more of the substance of the tumour, we should hardly think of describing such a tumour as a fatty or caseous growth. It still remains, as it always was, a carcinoma, some of the features or even capabilities of which may be affected by the degeneration of its substance, but whose tendencies will still be those of carcinoma. So, when a tumour—a sarcoma for example—presents here and there tiny nodules or plates of cartilage, we regard these tiny masses, and I believe with justice, as the result of organisation of the tissues which form the tumour; for cartilage and sarcoma tissue belong both to the connective tissue series. The material from which one of them is formed may equally be transformed into the other. I do not pretend to explain the law in accordance with which—in a tumour of the testis for example—one portion of this material is transformed into spindle-cells, another into cartilage, and perhaps a third portion into fibrous tissue. Nor do I know why the conjunction of cartilage with sarcoma is so frequent in spindle tumours of the testis; so rare as to be almost unknown in round-celled tumours; unless perhaps the impulse to organisation, which in the former results, for the most part, in the production of spindle-cells, and is there arrested, is sufficient at certain points to produce a more perfect tissue, and is even so powerful in some sarcomas as to transform nearly the whole mass into cartilage or fibrous tissue.

But this transformation of its substance does not produce a proportionate effect upon the nature of the tumour; it remains what it always was—a sarcoma—the features of which may be concealed, but whose tendencies will still be those of sarcoma. If the description of the three tumours mentioned above be referred to, it will be seen that neither of them is composed solely of cartilage. Each had a softer part or parts, consisting in the first case of what may fairly be described as round and spindle-cells, in the second of "fibrous elements," in the third of what is, somewhat loosely, called "connective tissue." It was this soft cell-tissue which in the first case extended up within the lymphatics into the pelvis. And in the second and third cases this soft tissue formed nearly the whole of the secondary tumour, so much so in one of them that the presence of cartilage could only be detected with the microscope. This latter circumstance is the more noteworthy because the primary tumour was almost precisely similar in the amount and disposition of its cartilage to the primary tumour described by Sir James Paget. This absence of organisation, as I should regard it, of some parts of the primary and of the secondary tumours, is often spoken of as if it were a sarcomatous degeneration of a tumour more highly organised. But there are several reasons opposed to this theory, among which I may mention, as perhaps the strongest, that the most recent tumours and most recent portions of the tumours are the least organised, or are not organised at all, and that there is no evidence of the previous existence of cartilage in the parts which are said to have thus degenerated. If the words "sarcomatous degeneration" are intended to convey that the secondary tumours are in their structure more decidedly embryonic than the primary growth, the only objection which can be raised against the expression is that it is not applied correctly.

No argument, however, will be so convincing as a comparison of these three cases first with one of pure cartilaginous tumour of the testis, next with those of the group of spindle-tumours, among which I have taken the liberty to include them, as Nos. 18, 19, and 23. This is an example of pure cartilaginous tumour.⁵ It had been growing four

³ Mém. de la Société de Chirurgie, tom. vi., p. 291.

⁴ Pathological Transactions, vol. xviii., p. 182; vol. xx., p. 331.

⁵ St. Bartholomew's Museum, Series 23-34.

years in the scrotum of a young man, twenty-two years old. Castration was performed early in 1875, and less than a year ago I saw the patient alive and in perfect health. The tumour is of small size, is composed of hyaline cartilage, which in its aspect and disposition resembles that of the malignant tumours, but there is no softer tissue present save a thin layer of fibrous tissue around and between the portions of cartilage.

On the other hand, it will be seen that the age of these patients is that at which sarcoma is common; that they do not differ from the other cases of the group in their relation to the scrotum, their position in the testis, their total duration, or their affection of the lymphatic glands.

The only characters of difference are the thickening of the cord in two of them, and consequent affection of the stump, and the affection of the kidney rather than the lungs in one—the former character an expression of greater rather than of less malignancy of the primary tumours; the latter distinguishing the case in which it occurred as much from the cartilaginous as from any of the other cases.

On the question of operation in cases of sarcoma and carcinoma I can say but little. For, while the few cases in which no operation was performed were all fatal, their fatality was a necessary condition to their enrolment in these tables; on the other hand, the large majority of deaths were of persons who had been castrated. But as the operation is not very dangerous to life, and as either disease is probably certainly fatal unless interfered with, the balance of opinion must be decidedly in favour of castration, especially as the good health of a few fortunate persons is recorded long after operation.

A PLEA FOR THE CLASSIFICATION AND DETAILED STUDY OF MENTAL AND SENSORY CAUSES, OR FORMS, OF SLEEPLESSNESS.

By JOSEPH MORTIMER GRANVILLE, M.D.

SLEEPLESSNESS—other than that occurring as a symptom, or in the course, of physical disease—is one of the commonest troubles the medical practitioner is called upon to treat; and it is not the least embarrassing. It is protean in its forms, and so complex and obscure are its “indications,” that the treatment it receives is practically a recourse to the expedient of stupefying the brain by opiates, chloral, or bromide of potassium, annulling the consciousness and mimicking natural sleep by an artificially-induced state, which may in some cases end in sleep, but is not itself sleep in any physiological sense, being a drug-created stupor. Thus is the difficult task of precise diagnosis avoided; while we compound for the discharge of the duty of special and direct treatment by overpowering the energies of self-consciousness. One of the first steps towards establishing a more satisfactory condition of matters, and introducing a better system of treatment, must be a deeper insight into the causes or forms of sleeplessness. I desire to bring under the notice of the profession a proposal for the classification of these causes or forms in, what seems to be, a natural order.

It may now, I think, be fairly assumed that neither Fleming, Crippie, Durham, Hammond, Sommer (arguing from the results of experiments made by Pettenkofer and Voit), nor any other of the many investigators who have tried to solve the enigma of sleep on physiological principles, has entirely succeeded. Each of these inquirers has contributed something to the sum of knowledge we possess about sleep; but, after all, the conclusion at which Vulpian arrived, simultaneously with other observers in this country, is probably the true one—namely, that the modifications of blood supply and pressure, which have in turn been supposed to be the causes of sleep or wakefulness respectively, are their concomitants or consequences. In short, the changes shown to take place in the rate of the circulation, and the size of the vessels of the brain, during sleep are the results, *not the causes*, of that state. Even in relation to the so-called “sleep” pro-

duced—or induced—by drugs, it seems probable that Vulpian is right when he sums up the inferences to be drawn from his own elaborate and careful experiments as follows:—“Le sommeil chloralique n'est donc pas dû, plus que celui qui est provoqué par l'éther, le chloroforme ou l'opium, à une anémie ainsi produite dans le cerveau. Nous pouvons donc dire que l'action hypnotique des diverses substances, que nous avons étudiées, sous ce rapport, s'exerce sans que les effets qu'elle produit puissent être rattachés à des modifications vasculaires des centres nerveux. Ces substances n'agissent pas, en effet, sur ces centres, par l'intermédiaire des vaso-moteurs, comme on l'a admis sans la moindre preuve directe; c'est sur les éléments anatomiques mêmes des centres nerveux que porte leur influence. Ce sont ces éléments qui sont directement modifiés, probablement parce que les agents en question y pénètrent et y produisent une altération histo-chimique.” In any case we are, I think, driven back from our speculations in physiology, upon the study of the mental and sensory phenomena in the search for a deeper and more accurate knowledge of sleep as a rhythmical function of life. Until new light is thrown on the subject of the actual and intimate causes of sleep we may most usefully direct our attention to the subjective experiences and objective characteristics of the act or state of sleeping; and it will help our inquiry, as well as facilitate the practical task of discovering remedies for aberrations of sleep, to classify the proximate causes, or forms, of sleeplessness.

There are two primary groups of manifestations. 1. The psychical, or mental, including such “sensations” as may arise from the mind making intentional or conscious use of the sense-organs. 2. The automatic, or sensory, comprising those intellectual acts or processes which are performed by habit, repetition, or what is called instinct, together with all the sensations which are involuntary and uncontrolled—or uncontrollable—by the will. To one or the other of these groups every cause or form of sleeplessness, not essentially morbid, may be referred. The annexed Table, a simple arrangement of bare clinical notes, will make my meaning evident. I am compelled by want of space to give only one of the tables comprehended in my scheme, and in the reproduction of that I have been obliged to omit all but a meagre sentence under each heading to mark its purport. The reader will, however,—if he approve the principle—have no difficulty in recalling the results of his own experience as to the symptoms and methods of treatment here indicated in rough outline. It is simply on the adoption of a precise method of classification I am anxious to insist.

Group I., as indicated in the Table, includes the causes or forms falling within the domain of the higher Consciousness, and probably located in the supreme cerebral centres, psychical in their character, and to some extent, at least at the outset, under the control of the will. They may be recognised as standing in close relation to some one of nine faculties or departments of consciousness—viz., thought, sensation (inclusive of the senses generally acting in concert), sight, taste, smell, hearing, touch, conscious muscular movement, and visceral-consciousness (that is, consciousness of what is going on in the viscera, or “feelings” and impulses taking their rise in or from the viscera). In respect to each of these forms of mental consciousness there are two varieties of Condition and two of State, *condition* being transitory, *state* more permanent. The consciousness may be accidentally thrown into a particular “Condition”; or it may, by persistence of an exciting cause or weakness, acquire a particular “State.” Thus there may be the Condition of “not being sleepy, or unable to sleep,” or that of “being too much engrossed to sleep”; and there are the States of “irritability” and “inability.” Under the heading “Not being sleepy, or unable to sleep,” in relation to *Thought* there may be simple wakefulness, with a disposition to think on any subject that suggests itself indifferently; or, in the absence of any special topic of formal consideration, imagination may disport itself wildly. In relation to *sensation* as a whole, there may be a condition of watchfulness or mental expectancy generally, the mind being, so to say, on the alert, keeping the senses awake; or in relation to the senses severally there may be troubles—e.g., *sight*, mental watching, with intolerance of the dark, and expectancy or fear; *hearing*, mental listening, awe-stricken or hopeful, with impatience of silence and wakeful imaginings of sound; or, disturbance in connexion with sensations of *taste*, of *smell*, of *touch*; longings or impulses for *muscular movement*, with a chafing sense of the restraint imposed by

OUTLINE OF A SCHEMA FOR THE CLASSIFICATION OF MENTAL AND SENSORY CAUSES, OR FORMS, OF SLEEPLESSNESS.

"Le sommeil général est l'ensemble des somnolences particulières."—BICHAT.

GROUP I. RELATING TO THE CONSCIOUSNESS: THE DISTURBANCE LOCATED IN, OR REFLECTED UPON, THE SUPREME CEREBRAL CENTRES.

Sleeplessness apparently due to the Conditions expressed by—				"Irritability."		"Inability."	
"Not being sleepy, or unable to sleep."		"Being too much engrossed to sleep."		Symptoms.	Treatment.	Symptoms.	Treatment.
Faculties causing or concerned in the Sleeplessness.							
Thought and imagination.	Symptoms. Thought active; imagination active when external objects are excluded. The senses kept on the alert by the will; watchfulness, mental expectancy of general sense impressions. ¹	Treatment. Interdict dozing by day. Discharge the energy of the cerebral centres by special work, such as reading aloud before going to bed. Change of the surroundings. Give the mind a sense of security by any simple arrangement. A warm bath before sleep.	Symptoms. Thought or fancy weary, but unable to get rid of some special subject which has taken hold of the mind. ³ Expectancy or imagination of a special set of sensory impressions haunts the mind.	Treatment. Encourage thought on the disturbing topic by day, and thus let the mind discharge itself before going to sleep. The special sensation engaged must be dealt with in detail, as below. Discharge the motor energy before sleep.	Symptoms. An irritable state set up by disorderly or painful thought. When no longer restrained by the surroundings excitement occurs. Mentally induced hyperaesthesia. When the attention is diverted, this form of irritability generally ceases.	Symptoms. A sort of mental "inability" to control thought. Ideal spectacles haunt the imagination.	Treatment. The performance of a task which can be achieved almost automatically — e.g., reciting verses from a dramatic poem. Sponging with very hot water (not a bath) immediately before going to bed.
Sight (mental or voluntary).	Symptoms. Watching, with intolerance of the dark. Real objects being invisible, images of thought are too vivid.	Treatment. Apply a bandage over the eyes before the light is extinguished. The will thus inhibits both mental and physical sight.	Symptoms. Thought so engaged with particular pictures of memory or fancy that it cannot put them away.	Treatment. Careful and slow inspection of a series of highly coloured pictures or portraits will displace the disturbing pictures of thought.	Symptoms. Irritability of mental sight, which renders the sufferer liable to spectra of fancy with intolerance of light.	Symptoms. Inability to see men- tally may be occasioned by inability to see physically, or it may be the effect of a mental weakness.	Treatment. Sleep in well-lighted room surrounded with near objects. Reading or thinking of subjects easily pictured by thought.
Hearing (mental or intentional).	Symptoms. Listening, with intolerance of special noises or sounds, and impatience of complete silence.	Treatment. Stop the ears with cotton-wool before trying to sleep. This inhibits the act of hearing, and gives rest.	Symptoms. Expectancy or imagination of special sounds, which has disturbed or agitated.	Treatment. The introduction of sounds which will help to divert the attention, as music or the ticking of a clock.	Symptoms. Irritability of mental or physical hearing, with acutely sensitive intolerance of sounds.	Symptoms. Inability to hear, real or imaginary, may be a cause of sleeplessness.	Treatment. Avoid sleeping on a partially deaf ear. Watch under pillow will often relieve, or the loud ticking of a clock.
Touch (in its direct relation to mental impressions).	Symptoms. Irritation caused by weight or texture of bedclothes. One form is the sense of "falling," when going to sleep on the back. ²	Treatment. Warm bath followed by cold douche or spray, and lying for some little time flat on the back on a couch before getting into bed.	Symptoms. Special expectancy in relation to touch. Common in children, and the aged in whom mental dispositions of childhood revive.	Treatment. To break up organised expectations or "feelings," change the surroundings; or yield for a time to the demands of consciousness.	Symptoms. Irritability, with hyperaesthesia of the skin, common in certain forms of mental disease, or established by habit.	Symptoms. Anæsthesia of the surface mentally induced, often hysterical, occurring at night, because the mind is thrown in on itself.	Treatment. The use of a bath and rubbing with towels of rough texture.
Taste (mental or voluntary).	Symptoms. Seldom general, but sometimes occurring, and then leading to an undiminished craving for food.	Treatment. The use of a flavoured lozenge will relieve and prevent the craving for food.	Symptoms. Special tastes may be heightened at night, or a taste ordinarily present be only then recognised.	Treatment. The use of a lozenge giving the flavour desired, or covering that which is distasteful.	Symptoms. Irritability of this sense. Often caused by rough or decayed teeth or ulcers on palate.	Symptoms. Inability to taste may occur in persons who have smoked excessively, or in the aged.	Treatment. The use of a strong lozenge (e.g., capsicum or camphor). Special treatment for local affection.
Smell (mental or voluntary).	Symptoms. An acute sense of smell often causes sleeplessness. It may be real or imaginary.	Treatment. Holding nose over steam before going to bed; as a palliative use scent or snuff.	Symptoms. A highly sensitive condition in respect to a particular odour, real or imaginary.	Treatment. Use scent gratifying the desire, or covering the unpleasant odour, real or imaginary.	Symptoms. Irritability of the sense of smell, continuous or recurring, may be specific.	Symptoms. Inability to smell, real or imaginary, is an occasional cause of sleeplessness.	Treatment. Local applications of a strong, stimulating character — snuff or douche.
Muscular-consciousness.	Symptoms. Fidgeting or twitching. When it occurs in muscles of hip-joint or elbow, causes dream of jumping or falling.	Treatment. Care should be taken to avoid supporting the body on a particular joint or limb. Warm bath relaxes muscles; cold braces.	Symptoms. The will set on grasping a particular object or maintaining a particular position; sleep impossible unless impulse be satisfied.	Treatment. Intentional abandonment of the idea inhibits the muscular action. Posture requiring some other action will counteract it.	Symptoms. A highly excitable state of the muscular system, choreic or hysterical, may arise from want of muscular work by day.	Symptoms. That accompanying paralysis, sometimes due to the weight of clothing. Mental night-mare.	Treatment. Remove all bonds and burdens, and place body and limbs in a half-flexed and free position before sleeping.
Visceral-consciousness.	Symptoms. The attention may be morbidly directed to any one of the viscera or their functions.	Treatment. Satisfaction of normal needs and impressions before lying down. Avoid late meals.	Symptoms. Special sensations in the viscera, or feelings engendered by them, may prevent sleep.	Treatment. The cause of these feelings should be investigated and treated directly. Divert attention.	Symptoms. Irritability of the visceral-consciousness common in hyper-sensitive and hysterical persons.	Symptoms. A feeling of inability to discharge special functions may cause sleeplessness.	Treatment. Special treatment for the cause. In cases of hysterical or morbidly disturbed states, a late meal relieves.

¹ "Systatica, irritation or inertness of the mind extending to the muscles or external senses; or of the muscles or external senses extending to the mind."—MASON GOOD.

² "Agrypnia Chronica: Habitual wakefulness; mind tranquil; attention alive to surrounding objects; mostly common to advanced age; found also occasionally in excessive fatigue, &c."—MASON GOOD.
³ A form of anæsthesia which impresses the mind with a feeling that the body has lost its support; caused, I believe, by partial stagnation of blood in the posterior columns of the spinal cord.

quiescence; or there may be mental impressions arising, or imagined, in connexion with some one or more of the visceral organs, which I propose to class as forms of *visceral-consciousness*. Again, the heading "Being too much engrossed to sleep" will include *thought*, busy or exhausted with a special task or subject of which it cannot rid itself: the *sensations* generally engrossed with a supposed duty of watchfulness, or severally engaged with and unable to leave a particular subject of mental *sight, hearing, taste, smell, or touch*; the *motor* faculty too busy with a special act to sleep, or the *visceral-consciousness* dwelling wakefully on a particular organic function. In like manner under the general heading "State," there may be continuous or recurring "Irritability" of any one or more of the several faculties, of the class which obtains when—by imagining—a "nervous" person so works on his mental sense of sight or hearing, that every wave of light or sound disturbs him; or, again, there may be conscious "Inability," with a distressing sense of powerlessness to perform some function, as when the knowledge that *hearing* is difficult so distracts or distresses the mind that sleep is impossible, the Consciousness worrying itself with the analysis of every imperfectly recognised sound, and thus creating a special cause or form of mental sleeplessness.

Group II.—which I have been unable to tabulate, but in outline resembles that presented—includes the common forms of sleeplessness related to the Sub-consciousness, being organised *habits*, probably located in the centres or combinations formed by the repetition of mental processes, and only partially under the control of the will, having passed into the class of "automatic" activities over which the lower or sub-consciousness holds sway, although—to revive a good old term—they may be *consensual*. The classification of this group is identical in its outlines with that indicated for Group I. Under the headings "Not being sleepy, or unable to sleep," and "Too much engrossed to sleep," we have the automatic faculty of *thought* exercising by the force of habit individualised methods, and carrying out special processes, of reasoning on every topic or subject that occurs to the mind. A clerk will reckon and calculate, a lawyer argue, a divine preach, a writer compose, in obedience to the law of habit, sleep being impossible. It is this form of disturbance which makes persons say they are "too tired to sleep," the truth being that the controlling faculty of Will is too weary to inhibit the automatic faculty, and they cannot go to sleep in a natural way, and are therefore sleepless. The *senses*, generally, may be actively watchful and wakeful, also in obedience to the law of habit, as often happens after a lengthened period of watching by a sick bed and the formation of a strong habit of keeping on the alert; or any one of the senses may be individually wakeful from custom. The sensory and muscular systems may be sleepless. Cases illustrative of this class of disturbances are of frequent occurrence; e.g., after a long voyage nervous or sensitive persons cannot sleep without the noise of the wind and waves, and that habitual balancing of the body which is induced by sleeping in a berth, or even in a swinging cot or hammock. Habits of function in relation to the *viscera* are also very common, and may be the causes of sleeplessness. Thus the bladder or intestine may contract a habit of discharging its contents at particular periods; and, partly from habit, and in part from the vascular and nerve changes incident to "going to sleep" or "awakening," there may be experiences in connexion with the organs of special function which disturb, and greatly distress if they are not explained. A not uncommon trouble of this class which occasions much distress and anxiety, when its nature and cause are unrecognised, is priapism occurring in the early morning. This is, I believe, generally the result of irritation of the cord in the process of its awaking; although sometimes it may be the effect of reflex action excited by urine in the bladder. Under all these forms of Condition the faculty which is in the habit of working at night cannot sleep, and being unable to perform its accustomed labour disturbs the whole body, by fruitless and fidgety endeavours. States of "Irritability" and "Inability" affecting the automatic sub-consciousness are likewise common causes of sleeplessness, as when a habit of sleeping in the dark renders the dullest light a cause of sleeplessness, although there is no trace of intolerance of light by day.

The key-note of the classification proposed may be found in Bichat's aphorism, which I have set at the head of the table, "Le sommeil général est l'ensemble des sommeils particuliers." The several sleeps composing general sleep do not commonly occur simultaneously or last during equal periods.

The order of their occurrence in "falling asleep" seems to be—1, muscular-consciousness; 2, sight; 3, hearing; 4, smell; 5, taste; 6, thought; 7, touch. This is a broad statement, and will be found only approximately accurate; the succession varying with the individual organism and habit. The order of awakening is, again speaking generally, inverse. The rest enjoyed by each system contributes its share to the grand result, and the relative proportions of the several sleeps compounded determine the character of the phenomenon as a whole. It follows that the converse is true with regard to the nature and causes of sleeplessness. The general character of the "sleeplessness" from which a patient suffers, and the plan of treatment most likely to be successful in his cure, can best be ascertained by recognising the particular *cause* or *form* of the wakefulness; and this may be most readily made out by noting the prominent symptoms, and determining the class and group of the natural classification to which they belong. If any one should contend that the phenomena I have noted and classified are not causes but simply symptoms of sleeplessness, he may regard them as *forms* of the trouble, and it will still be open to him to accept, at least in principle, the grouping suggested.

The differential diagnosis of the two groups of causes or forms of this trouble is of the highest importance, because the principles and methods of treatment are not identical for the corresponding conditions and states, or even for what appear to be precisely similar symptoms or indications. Thus, for example, the characteristic feature of the phenomena in Group I. is the element of Self-consciousness which declares itself, or may be detected, as a conspicuous part of each experience. The Will has a limited, but *only* a limited power, over the functional or organised habits of the sense organs, the muscular and visceral systems, and, even, over those tracts or departments of the brain which are concerned in sub-conscious cerebration. It can sometimes inhibit particular actions or interrupt the discharge of special energies—or energy striving to act in specific directions—which habit has liberated. It can, so to say, block the line of least resistance. The Will is not, however, directly or actively concerned in the causes or forms of sleeplessness classed in Group II., unless it interposes, because every process of thought or action which has become organised by repetition and become a *habit*, has passed out of the domain of the supreme faculty of the Consciousness into the series of automatic activities controlled by the Sub-consciousness. Whereas the will *is* directly and actively concerned in the causes or forms of sleeplessness included in Group I. It follows that while the treatment for the disturbances in Group II. must be indirect, and so aimed as to operate through the senses chiefly, that adopted for the relief of the troubles classed in Group I. must, in some way, act immediately, or, at least, very directly, upon the Will and Consciousness. Mental diversion will relieve the symptoms of the *first* group, whereas it is not unlikely to intensify the wakefulness arising from troubles of the *second* group, although at a glance these may seem identical in form with the others. The intensifying of automatic actions when the self-conscious attention is diverted is well understood. The restraint of the Will being withdrawn, "impulse" or "instinct" has unqualified control of the organised brain and nerve-centres. Another matter not so commonly recognised is the fact that if the Will be pressed or permitted to interfere for the amendment of a troublesome *habit*, it generally increases the trouble by irritating the nerve-centre or combination which has been formed, by repetition, for the performance of the particular act or process it is desired to control. The centre not having been constructionally disciplined for control by the Will resents the authority that faculty now tries to exercise over it. If an expert and practised pianoforte player were to try to make the fingering of each chord a voluntary act, he would be unable to play, and throw himself into a fever of excitement. This is what happens when the essential difference between the two classes of phenomena classed in Groups I. and II. is not perceived, and the voluntary method which is likely to be useful in the one case is misapplied in the other. The discrimination is not always easy, but it is indispensable that it should be made. The history of the case and the known effects of Attention in relation to the seeming cause of the wakefulness will generally enable the practitioner to determine the group to which a particular phenomenon or symptom belongs; but he must make the discrimination for himself, because nothing is more unwise or

conducive to failure in these cases than to ask leading questions. The examination should be so conducted as to avoid giving the patient the slightest clue to the nature of the investigation pursued. Even when the cause of sleeplessness has been recognised, it is, except in rare instances, undesirable that the patient should be informed of the precise nature of the disturbance. If the cause belong wholly to the second group, and is a matter of habit, it is almost always essential that he should be kept in ignorance of the trouble from which he suffers, while it is treated through the surroundings or indirectly.

I am not asking medical men to over-estimate, still less am I wishing them to treat, symptoms, but to search for the causes of disease by tracing back to their several sources the divers forms of an affection which may spring from any one of a large number of disturbances. There is no means of getting at a disease, and acquiring an intimate and precise knowledge of its nature, except by studying the formulæ of its manifestations; and there is no safe way of selecting a method of treatment except by observing carefully the indications for treatment which are supplied by these same formulæ. I know well that the bane of modern science is the exaltation of the analytical over the synthetical method of research; but here we are face to face with a symptom too often regarded as a disease. We do not know what it is. It has never been, so to say, picked to pieces, and we have hitherto treated it *en bloc*. Not being able to ascertain what it is keeps a particular patient awake, we exhibit a so-called "soporific," which will stupefy or intoxicate him until he falls into a state of unconsciousness, and, in the end, perhaps, sleeps! The practice is not, possibly, less scientific, but it is certainly not one whit more so, than to treat pains in the epigastrium with pepsin, without taking the trouble to inquire whether there is any organic disease, whether the food taken is digestible, whether it is properly masticated, or whether the patient is suffering from excess, or, it may be, starvation. We cannot proceed a single step on the way to treat Sleeplessness intelligently until its form, in each particular case submitted to us, is definitively ascertained, and the cause of wakefulness clearly made out; therefore, I plead for the recognition and classification of those ideational and sensory forms, or proximate causes, of sleeplessness which are too commonly overlooked.

London.

PAROXYSMAL OR INTERMITTENT HÆMATURIA IN A YOUNG CHILD FOLLOWING SUPPOSED INJURY.

By W. H. DAY, M.D.,

PHYSICIAN TO THE SAMARITAN HOSPITAL FOR WOMEN AND CHILDREN.

J. L—, aged three years, a healthy and well-developed child, was admitted into the Samaritan Hospital under my care on Nov. 14th, 1879, having passed blood in her urine twenty-four hours previously, *unaccompanied by pain*. The urine then became quite clear up to the time of her admission. Blood had been noticed in the urine for a month past, but this last attack alarmed her parents.

History.—The mother stated that a year ago the child fell downstairs, and for the first time in her life she passed blood in her urine for three times succeeding this accident. The bleeding did not recur till July, 1879, when it lasted only for one day; then five weeks elapsed, and it recurred once more for one day only. There was no further return till shortly before admission. The father and mother were both healthy, and had always resided in London. There was no history of measles, scarlet fever, or constitutional syphilis. The heart, liver, spleen, and lungs were healthy; the temperature was normal and the bowels regular. The child complained of pain when pressure was made over the loins, but no decided indication of suffering was shown when pressure was made on either lumbar region.

On the day following admission the urine was of acid reaction, sp. gr. 1022; it had the appearance of muddy water and threw down a thick deposit, which was rendered

clearer by moderate heat; it remained slightly clouded on boiling, and did not become clear by nitric acid. The colour was due to the admixture of uric acid crystals with blood, showing that there was hæmorrhage from the kidneys, but there was no free clot. On a microscopical examination the deposit was found to consist almost entirely of uric acid crystals, with a few epithelial casts and red corpuscles.

The child was put on a milk diet, and kept in bed. A mixture of bichloride of mercury, with the tincture of the perchloride of iron, was ordered three times a day.

Nov. 19th.—There was a deposit of rather dark, coagulated blood at the bottom of the test tube. Seven ounces of urine were passed in the twenty-four hours.

20th.—Urine smoky and albuminous. Six ounces passed during the night and day. A mixture of tincture of perchloride of iron, with diluted hydrochloric acid, was ordered.

22nd.—Urine smoky, sp. gr. 1022, acid, throwing down a turbid deposit, the lower part of which was reddish; bowels regular. She occasionally cried at night from pain across her loins, which prevented her from sleeping, the pain generally lasting about half an hour.

24th.—A good deal of bronchial catarrh. Iron mixture discontinued, and squill and ipecacuanha ordered for the cough.

27th.—Cough better. Since the iron mixture was given up more blood was passed in the urine, some specimens being like port-wine and water. The average quantity of urine passed during the past three days was $11\frac{1}{2}$ oz., $7\frac{1}{2}$ oz., and $9\frac{1}{2}$ oz.

Dec. 9th.—On an average since last report the child passed daily from 10 oz. to 14 oz. of urine, having a sp. gr. of 1024, some specimens being clear, and others containing blood of a dark port-wine colour, settling at the bottom of the vessel in a coagulated mass. In one of the specimens there were numerous hyaline casts, and an abundance of free renal epithelium with uric acid crystals. Constitutionally the child appeared well, the tongue was clean, she never vomited, and the bowels acted twice a day. There was no puffiness of the face nor anasarca. Two teaspoonfuls of a mixture, containing gallic acid and sulphuric acid, were ordered to be taken three times a day.

15th.—The urine has continued perfectly clear since the 9th without any deposit of blood. Sometimes the morning urine was perfectly clear, that passed in the evening throwing down a copious whitish deposit, which became clear on boiling (lithates).

Jan. 8th, 1880.—No return of blood in the urine, on an average the patient passed 15 oz. of urine during the twenty-four hours. General health good.

14th.—Urine very clear, acid, unchanged by boiling; no blood or albumen. To omit all medicine.

Feb. 3rd.—The urine remained perfectly healthy since last report, although she had been up and about the ward. She left the hospital on this day.

13th.—Readmitted, passing bright-coloured blood with her urine.

April 1st.—There was no return of blood except fourteen days previously, when a small quantity again appeared in the urine, and since then it had varied considerably, some specimens containing blood and some none. For the last ten days the urine remained clear. The child was pallid, but there was no sign of anasarca, no headache or disinclination for food. Heart-sounds normal. The gallic acid mixture was resumed. Milk diet.

25th.—The urine was perfectly clear; sp. gr. 1028; acid reaction; in every respect normal. The child left the hospital with directions to continue the gallic acid mixture, and to return again if blood made its appearance in the urine.

Three weeks after leaving the hospital she had only passed blood in the urine once, and then she had catarrh and cough.

Remarks.—This case is very interesting from several points of view. Looking at the history, the absence of the exanthemata, and the general good health of the parents and the child, it does appear that the injury was the starting-point of the hæmorrhage, which came on for the first time the day following the accident, and that once originated, absolute rest and a milk diet were necessary to arrest it. Only falls are such common accidents among children that the injury in this case might be a pure coincidence. With regard to medicine, the remedy that did most good—in fact, which alone never failed to control the hæmorrhage—was gallic acid. At no time was there any rigor or elevation of temperature, nor any diminution in weight. The

chief noticeable change was an increase of pallor in the patient, which was no doubt in a great measure due to confinement to bed and the suspension of all animal food.

Dr. Greenhow has recorded some very interesting cases of "intermittent hæmaturia." In one of his cases, a boy eight years and a half old was first seized with hæmaturia when two years of age. The attacks were preceded by shivering and thirst, and whenever the boy got chilled the urine became of a dark colour, sometimes as though blood were mixed with it, at other times like black beer with a froth upon it. "During the attacks the boy generally had stiffness and weakness of the legs, so that he could scarcely walk, and his feet sometimes became of a purple colour, and swelled so much that he could not put on his shoes; his ears also frequently became cold, purple, and painful to the touch. More rarely his hands swelled and became purple during the attacks. The first urine passed after the shiverings had always been dark-coloured, the second less so than the first, and at the third or fourth micturition the urine generally resumed its normal appearance."¹ This case differs from some of those recorded by Dr. Greenhow and others in the absence of a malarious history, rigors, sweating, and febrile symptoms. The child, with the exception of being rather pale, was perfectly healthy-looking, and there was an absence of sallowness which has been often observed in some of these cases, particularly when the hæmaturia has been associated with the oxalic acid diathesis. Dr. Greenhow regards the affection as a form of dyscrasia—a disease of the blood rather than of the kidneys. I should say that Dr. Greenhow's explanation given above was suitable to my case, whilst I do not altogether ignore the possibility of some injury being received when the child fell downstairs, thus exciting a degree of renal congestion which was the starting-point of the evil. The presence of free blood certainly points to intermittent renal disease as well as pure hæmaturia; still, in all other cases of paroxysmal hæmaturia the theory that no kidney affection exists has yet to be proved; for we must never forget, as Dr. Legg has reminded us, that no record exists of any examination after death of a patient who during life was subject to paroxysmal hæmaturia.

Dr. Godson² relates a case of paroxysmal hæmaturia in a little girl, two and a half years of age. Each attack was preceded by rigors. As in my own case, uric-acid crystals were found in abundance in the urine, and likewise gallic acid was administered with equally good results in both cases. According to Dr. Wickham Legg's exhaustive record of the literature of this disease,³ uric-acid crystals have previous to Dr. Godson's case been observed in two cases only. The presence of free blood and the absence of initial rigors distinguish my case from most others. It may be considered as paroxysmal hæmaturia in the literal sense of the latter term; whilst the more frequent form, where rigors are observed and no red corpuscles can be found in the blood, is strictly hæmaturia.

Manchester-square, W.

INSANITY: ITS TREATMENT AND PREVENTION.

The Presidential Address for 1880 of the Border Branch of the British Medical Association,

By J. A. CAMPBELL, M.D., F.R.S. EDIN.,
MEDICAL SUPERINTENDENT, GARLAND'S ASYLUM, CARLISLE.

It is difficult for one busied in the treatment of insanity himself to speak generally of the treatment in the country at large in an unprejudiced manner. I shall just tell you what I have noticed during the fifteen years I have studied and treated insanity, and afterwards touch shortly on the present treatment. I have noticed the following:—An increasing tendency to examine into the physical condition of the insane. To look for, and in the majority of cases to find, bodily causes for mental manifestations, and to keep careful and systematic records of cases, and in doing this to make use of instruments of precision available in medical practice, and a persistence in this in spite of the difficulty caused by the

patient's state. An intelligent and accurate inquiry into the use of various therapeutical remedies, and this by not a few but many observers. A markedly greater interest in pathological research, and even without discussing the advantage of making post-mortem examinations in each case from scientific or educational points of view. The greater security given to the life of patients, and the safeguard from injury resulting from such a procedure, must commend it even to the non-professional mind. In 1878 out of 4715 deaths which took place in English asylums, 2349 autopsies were made. A greater tendency to give individual liberty to convalescents or patients who seem harmless, and at all to be trusted. A clearer idea as to the necessity of continued treatment and care in an asylum, and a consequent shorter residence after recovery in certain cases. A fuller realisation of the value of employment as an aid to recovery. An increase in outdoor exercise, especially for female patients. In most well-conducted asylums nowadays few if any patients whose bodily health permits of it are restricted to the house, or what used to be called "airing yards"; and where these were walled in and devoid of all vegetation, where the patients saw nothing but the sky and the side of the asylum, this must have been a great advance, as some superintendents point out *in extenso* in their reports. To many of us it appears wonderful that such places should have been invented at all. A freedom from the sort of asylum horror which at one time existed at the terms "seclusion" and "restraint"; a conviction that the use of either when really requisite will not bring back their universal use; and a recognition that in certain forms of excitement, such as epileptic, and also delirious excitement in general paralysis, seclusion is not only permissible, but the safest and best treatment for the patient. A growing knowledge that hitherto the staff of attendants has been proportionately small for the work both of day and night nursing, and that, no matter how much may be written on the getting and keeping good attendants, yet, like most things, it resolves itself into a money matter. Facilities for all medical men becoming acquainted with insanity and its treatment, which at one time did not exist. Theoretical and practical teaching of insanity is now the rule in all medical schools, and the contiguous asylums are available for teaching purposes. For those who wish a further acquaintance with the subject there are numerous clinical clerkships easily obtainable, affording asylum residence and practical instruction. The present and future medical student will be almost culpable if he does not make himself fully conversant with at least certain portions of this subject.

Now as regards the treatment of the present day. In most if not in all asylums everything is done with the view of promoting the recovery of recoverable patients, and affording comfort, care, and safe keeping to those in whom recovery cannot be expected, and great amelioration in state is often brought about to the latter in health, habits, and mental condition by treatment and assiduous attention. It is quite recognised that cleanliness, order, discipline, personal tidiness, neatness and elegance of surroundings are all to be desiderated, and are important elements in the general treatment; but it has also to be kept in mind that with working patients engaged in farm and other manual labour, a spick-and-span appearance of person and attire, and a state of extreme polish and order as regards the wards, though it may gain ephemeral praise for the superintendent, can only be estimated at its proper value when considered along with the other working of the asylum as a whole. Dutch houses, though clean to a degree, are said to be wanting in comfort, when it is necessary to go in at the back door for fear of soiling the front door-steps. Unless the material comforts are considered, magnificent ball-rooms only very occasionally used, corridors with flowers seldom traversed by the patients, and grounds tastefully laid out and seldom frequented, do little to aid recovery or promote happiness in those whose life has to be passed in an asylum. County asylums are built and furnished for the care, comfort, and ordinary life of, principally, the working classes, not to excite the amazement and wonder of casual visitors.

Now as regards direct medical treatment. Few medical men believe that insanity—a disease which comes on slowly, which in the majority of cases has been produced by a breach of many of the most ordinary laws of health, and which in the vast majority of cases is found with the impaired bodily health to be expected from such a course of life—will ever be cut short by a dose of medicine, or cured instantaneously by any means. All are united in believing that

¹ Clinical Transactions, 1868, p. 44.

² Notes of a Case of Paroxysmal Hæmaturia. St. Barthol. Hospital Reports, vol. xiii., p. 165.

³ On Paroxysmal Hæmaturia. Ibid., vol. x., p. 71.

patients should be placed in healthy localities with pleasant surroundings; that recovery of bodily health is the first step; that employment, recreations of various kinds, and even routine devotions are all means to the end. So far as I have read in asylum reports, asylums in this country have been very exempt from zymotic diseases, but several have suffered severely from diseases consequent on imperfect drainage. For the last few years this subject has received general attention, and I should think that enteric fever and erysipelas will soon be spoken of as diseases which used to occur in asylums.

I last year laid before you a *résumé* of my practice during the five years ending 1878, in dealing with the excitement met with in mania, puerperal mania, general paralysis, and epileptic insanity. I pointed out the variability of the duration of the attacks of excitement, even in repeated attacks in the same individual, and the necessarily extreme difficulty of accurate estimation of therapeutic treatment. I discussed the question of the value of sedative treatment by day and of hypnotics given at night to prevent undue waste in recent curable cases, and also in chronic patients, and the action of protracted out-door exercise, and its influence as a calnative by expending in muscular exertion the nervous energy which would otherwise eliminate itself in noise or violence. I also touched on other agents useful in treatment. I found that sedative treatment during the day was at times necessary to render patients manageable, but when used for any length of time the patient remained somewhat longer in a stupid or mentally clouded state after the excitement passed off.

In acutely excited cases, where sleep could not otherwise be produced, it should be caused artificially, but this treatment should not be long continued. In my experience chloral in twenty or thirty-grain doses given in sherry was the most certain sleep-producer and harmless, all that was wanted being to set the patient to sleep, not to cause continued drugged sleep. I gave corroborative evidence, based on six years' experience, as to continued treatment with bromide of potassium in reducing the number of fits and allaying irritability, the most disagreeable and difficult feature in epileptic insanity.

I also expressed myself very strongly as to the value of prolonged out-door exercise, that by it the necessity for sedative treatment is much diminished, and insomnia seldom present. I have since then conducted my practice in accordance with these views, and have had most satisfactory results.

So many careful and accurately recorded papers have appeared in the medical journals dealing not only with the sedative qualities of different medicines, but also their effect on the system as regards nutrition, &c., that I do not touch on the subject. I think, however, that the concurrence of opinion of careful observers in asylum practice questions a direct curative action from sedative treatment, while quite admitting its use to enable an acute attack to be safely and more easily tidied over.

In general paralysis no means of treatment hitherto adopted has much retarded, far less cut short, the course of the disease.

Delusions of a fixed character in persons otherwise possessed of mental capacity and in the enjoyment of good bodily health, have as yet proved an unsolved problem, and even after death we are left in the dark concerning their cause for the most part. Though each year, owing to increased care in treatment during attacks of excitement, fewer cases lapse into dementia, yet it is sad to think what a mass of human beings, well grown men and women who outwardly appear well, who, I have no doubt, have still their faculties though in a clouded and dormant state, wanting a something to bring them into action and subordinate them to an acting will, still remain monuments of our inability to prevent such a state, or to galvanise their mental powers into action. I believe we shall yet find a means of stimulating some of them into mental activity. Two forms of treatment emanating from the other side of the Channel call for notice. Dr. Ponza proposed a treatment by coloured light, light admitted through stained glass windows, the walls of the room tinted to match the coloured light. He found that keeping patients in red rooms was good for melancholia, blue rooms for excitement. He reported cases, strongly insisted on the value of the treatment, even in apparently hopeless cases of insanity. In one asylum that I know in England the treatment was tried without result. In France lately much has been written of the

efficacy of metallic application externally in cases of nervous disease of a hysteric type—hystero-epilepsy. Numerous medical men have witnessed these applications and their good results. I confess myself sceptical of such forms of treatment; they savour to my mind of the records of Arabian physicians and sages. In this country all agree that though nervous affections of a hysteric character may originate from one locality or one set of organs, yet the treatment, founded on common sense and experience, should be general, to improve the bodily health, to use all moral means to make the patient live more outside herself, and get rid of perverted sensations, thoughts, and actions, and as far as possible to distract attention from the sources of such. Before I leave this portion of my subject I may briefly allude to two topics which are at present under consideration, and which may in future influence the treatment of insanity.

One is the entire separation of the recent from the chronic insane. No one would hastily give an opinion on such a subject without experiment. In the metropolitan district, where there are immense numbers of quiet demented, this mode has been found to answer well; but in counties, where the total amount of lunatics is under 800, I question the advisability of a separation on the ground of expense and difficulty of working. Chronic patients require better diet than the workhouse scale, and if you withdraw their working assistance, poor though it may be, from the asylum for recent cases, you greatly increase the cost of the latter. I believe up to 600 a mixed asylum works best. Many whose opinion is of value expect very shortly a change in lunacy legislation, which will affect private asylums, and also the boards of management of public asylums, giving in the latter a more direct representation to the ratepayers. The position of the medical proprietors of private asylums appears to me a delicate and difficult one, though it may be money-making, and I think if fair terms are offered, as certainly should be in a country like this if the State interferes, that medical proprietors should hail with joy any legislative interference which will free them from a position of difficulty and unmerited suspicion.

As to a change in committees of county asylums. From the humane and kindly, as well as from the economic (in the true sense) manner in which these institutions have been managed, and the feeling of security and faith in the good treatment of the inmates that is held in most counties, I do not believe that any material change will be made that will hamper the working or cause retrogression in treatment, especially in those asylums which are abreast of the times, and whose staff are conscientiously carrying out the proper aims of the asylums.

Before making any radical change in committees who have individually, with no sparing of time, trouble, or expense, devoted themselves to the carrying out of the Lunacy Acts in their respective counties, there ought, of course, to be an inquiry made into the present state of matters, and if changes occur proper provision for effecting such changes will surely be made. In a subject of such great importance to thousands unable in any way to see to their own interests, legislation ought not to be hasty, imperfect, or too tentative.

At first glance it may appear utopian to expect that insanity can be prevented by any means which are at present in our power; until lately, however, the same was said and thought about several other diseases. We know that an inherited faulty formation of bone may be prevented or lessened by proper attention to diet on the part of the mother during pregnancy and the child during growing life. That other inherited diseases, such as gout and rheumatism, may be warded off during the life of one generation, and the tendency to them reduced in the next by constant care and attention to habits and diet. That many ephemeral bodily diseases are the result of carelessness and indulgence is well known, even outside the profession. Every one knows the consequences of festal seasons, but I doubt whether the changes in structure of vital organs caused by excessive eating and drinking are properly realised, except by those who are in the frequent habit of making post-mortem examinations. Now, whether for treatment or prevention in dealing with purely physical diseases, physicians at once examine into, and, if possible, ascertain the cause. With a disease like insanity, which has mixed manifestations, which is strongly hereditary, which is often called into existence from a latent state by not one but many causes, and last, but of great importance, where the sufferer,

unlike what exists in most diseases, is unable to give an account of the invasion of the disease, of the variance in his habits of life from the normal, to account for this serious change in his condition and state,—in fact, in most cases, the principal actor in what has caused the disease is by the disease prevented from giving any information about it. This is a serious obstacle to research as to the causation of insanity, and it entails a necessity for greater and more careful investigation from collateral sources.

We know that old writers ascribe the absence of epilepsy in ancient days in Scotland to the castration in youth of all the males who took fits, and that by this the propagation of the disease was stopped. This treatment, though rough and against the sentiment of the present time, was no doubt efficacious. The shutting up in asylums of those who labour under mental disease to such an extent as not to be able to take care of themselves—weak-minded, erotic, and epileptic girls and youths—must undoubtedly stop what would be almost inevitable in these cases, the procreation of a nervously diseased set of illegitimate children. Even within the last thirty years or so was it the case that silly, weak-minded, or idiotic females, in whom the physique was at all developed, fell an easy prey to any seducer, and were often the parents of a succession of children, many of whom, if not all, were likely to be imbecile—at any rate, if they escaped at birth, far more likely than those of healthy descent to be affected by nervous disease at the critical periods of life. The present asylum system to a certain extent provides against this in cases which manifestly are quite unfit to be at large; but there are many of the class I allude to at large, spreading the mischief. So much for the prevention by transmission by those clearly insane or markedly weak-minded.

(To be concluded.)

REMOVAL OF THE RIGHT LOBE OF THE THYROID.

By F. A. PURCELL, M.D.,

SURGEON TO THE CANCER HOSPITAL, BROMPTON.

SARAH S. R.—, single, aged twenty-three, a strawplatter, from Dunstable. About three years and a half ago this girl noticed a slight enlargement in her neck, most towards the right side. Since then it has been steadily increasing, giving no pain. General health good. Catamenial discharge regular. She knows other women in the neighbourhood who have enlarged thyroids, and a patient in the hospital from her neighbourhood has goitre. The water at Dunstable is chalky. She attended the out-patient department for eight months for goitre, during which time all the usual remedies (ointments, liniments, &c.) were studiously applied without diminution in the size of the swelling, but rather a slight increase. At her earnest solicitation she was admitted to the hospital to have the growth removed.

Upon admission there was a tumour about the size of a large duck's egg at the right side of the neck, extending from about the third ring of the trachea to the upper border of the thyroid cartilage, overlapped by the edge of the sterno-mastoid muscle, yielding an indistinct sense of fluctuation. Also some thickening of the isthmus of the thyroid body, the whole moving with deglutition; at the same time with a sense of free movability in itself.

July 20th, the patient being under an anæsthetic, I made an incision two inches and a half long over the tumour along the anterior edge of the sterno-mastoid, avoiding the external jugular vein, which was nearer the middle line than normal. The mastoid muscle being drawn outwards with retractor hooks, I proceeded to break down the adhesions with the point of the forefinger and handle of the knife, and experienced some difficulty, as the adhesions were tough and fibrous in character. Having broken through some large branches from the superior thyroid artery, there was brisk bleeding till the ends were secured and tied with catgut ligatures. I now succeeded in quite turning out the right lobe, and came to the isthmus, which was considerably enlarged. This I detached from the trachea, getting well over to the left side, and secured it tightly in a catgut ligature before applying the knife. There was now hardly any bleeding, but a large cavity

existed at the lower end, extending well down towards the clavicle and the large vessels of the neck externally. A horse-hair drainage-tube was put in and the wound closely united with horsehair sutures; the carbolic spray, 1 in 20, playing on the parts all through, all strict antiseptic precautions (Listerian) being observed during and after the operation.

For twenty-four hours the patient complained of difficulty in deglutition, which was her only trouble. Union throughout took place by first intention, without a drop of pus at any time, the drainage-tube and sutures being removed on the tenth day. Discharged from hospital on August 7th. Upon examining the growth after removal, it was found to be made up of a number of small cysts with thin walls, one larger than the rest at about its middle. Anteriorly it was irregularly conical and prominent, posteriorly flat, and very dark livid in colour; it measured three inches and a quarter in length and seven inches around its largest part.

Manchester-square, W.

REPORT OF THE FIRST CASE OF OVARİOTOMY IN BARBADOES.

By F. B. ARCHER, M.B., C.M.

MARY B—, aged nineteen years, single, was admitted into the General Hospital, Bridgetown, Barbadoes, on August 11th, 1879. She first noticed a swelling of her abdomen eighteen months ago, more conspicuous on the left side. Had occasionally a little pain, but not much. Catamenia always regular. Has lost flesh, but is fairly nourished.

On the 11th September, at 2 P.M., the patient was put under chloroform and an incision three inches and a half long was made, extending from above the pubes to a little below the umbilicus. A few slight adhesions were now broken down, a trocar inserted, and nineteen pints of fluid drawn off. The cyst (which weighed 4½ lb.) was removed, the pedicle (a small one) was secured with a silk ligature, cut short and returned into the abdomen. The abdominal cavity was carefully sponged out with a solution of carbolic acid, all bleeding arrested, and the wound closed with nine silk sutures. Dry lint was placed over the wound, strapping and a bandage were applied, and the patient returned to her bed in the ward with the other patients. The operation lasted three-quarters of an hour. She vomited once only. In the evening the catheter was passed; she had ice to suck; one-sixth of a grain of morphia injected hypodermically; no vomiting; no pain. Temperature 101.4° F.

Sept. 12th.—Morning: Slept several hours last night. One pint of urine drawn off; one-sixth of a grain of morphia injected; nutrient enema given, and to be repeated every fourth hour. Evening: No pain, no sickness; seems to be getting on well. Temperature 100°.

13th.—Allowed some milk and beef-tea by the mouth to-day; nutrient enemata stopped; passes water naturally. Temperature 101.8°.

14th.—Had a good night. Temperature 99°.

15th.—Wound dressed; very little discharge; going on very well. Temperature normal.

16th.—Six stitches removed to-day; allowed to take soda water and brandy.

17th.—Wound dressed and the remaining stitches removed. Evening: Temperature 101°; pulse 120. She says she feels very well.

18th.—Had a good night; an enema was administered, and the bowels freely opened; allowed chicken for dinner. Temperature 100°.

19th.—Temperature normal; going on well.

From this date her temperature continued normal. On the 28th the wound was healed, and she was allowed to get up. Her bowels only move after enema. She remained in hospital some time longer and rapidly regained her flesh and strength. We had no apparatus for carrying out the antiseptic treatment, or it would have been used. She remained in one of the ordinary wards of the hospital along with the other patients.

This is the first time the operation has ever been performed in this island.

Bridgetown, Barbadoes.

LONDON HOSPITAL.

AN UNUSUAL CASE OF LAMENESS; OPERATION; CURE.

(Under the care of Mr. FREDERICK TREVES.)

THE following somewhat peculiar case came first under observation in January last.

The patient was a perfectly healthy lad, sixteen years of age, well developed, vigorous, and free, so far as could be ascertained, from constitutional defect of any kind. He complained simply of great pain in the left foot when he attempted to walk, and this made him so lame that he had difficulty in walking to and from the house where he was employed, and where his employment, it may be noted, was sedentary. This lameness had existed for exactly a year, and was becoming more troublesome every month. The first occasion on which he noticed the pain in the foot was one evening when pulling off his boot. There was no history of injury of any kind, direct or indirect, nor could the patient account for the defect in any way. On examining him it was found that he walked just as a person would walk who had a tender spot on the inner side of the sole, that is to say, he walked as much as possible on the heel and outer side of the foot, a fact also well demonstrated by the unequal manner in which the sole of the boot had been worn away. On inspecting the foot it appeared perfectly normal. On being asked the seat of pain the patient pointed very precisely to the web between the great and the second toe, and to a spot exactly opposite to the metatarso-phalangeal joint. He spoke of the pain as being extremely severe, and as occasionally running up the front of the leg to the knee. It only came on, he stated, when he attempted to walk, or accidentally or purposely bent the great toe. After he had walked some distance the pain would continue perhaps for one hour, but otherwise when the foot was at rest he was perfectly free from discomfort. The metatarso-phalangeal joint appeared quite normal; there was no heat, no swelling, no tenderness, and not the least pain on interarticular pressure, and no pain on movement except when the great toe was flexed towards the dorsum. Forcible extension towards the sole was painless, as was also any rotatory movement, but when an attempt was made to flex the toe the pain was immediately induced at the spot indicated.

It was obvious so far that the pain produced by any attempt at flexion of the great toe caused the lameness; flexion at the metatarso-phalangeal joint being a necessary movement in the ordinary act of walking. It was possible also to understand that the act of removing the boot would be painful by the flexion of the toe almost necessarily caused in its withdrawal. On again manipulating the parts, it appeared that the base of the first phalanx of the great toe was a little more prominent than usual. The corresponding phalanx on the opposite foot presented exactly the same degree of prominence, and the enlargement seemed to be purely anatomical. The conclusion arrived at was that in the act of flexion the base of the phalanx was for some reason carried against the digital nerve situated in the web, and it was conceived that such a circumstance would account for the character of the pain, and its occasionally following the course of the anterior tibial nerve. It was found, too, that if the tissues of the web were drawn away from the great toe as far as practicable, the toe could then be flexed without pain.

Esmarch's bandage having been applied, an incision was made in the web, and the digital branch of the anterior tibial nerve was fully exposed. It was then found that the flexion towards the dorsum, the base of the first phalanx of the great toe, was carried forcibly against the nerve, but that in the opposite movement of extension the nerve was not touched. The prominence spoken of was obviously only anatomical, and might have been more apparent than

real, and produced by some inequality in the joint surfaces. About a quarter of an inch of the nerve, which appeared to be quite normal, was removed, and the wound was closed and dressed with dry lint. It healed without trouble, and the patient then found that he could walk without inconvenience, and that flexion of the toe, however violent, could no longer induce pain. He was seen about a month after he left the hospital, and he was then in every respect perfectly well, and had lost every trace of his lameness.

WESTERN DISPENSARY, EDINBURGH.

CASES FROM THE THROAT DEPARTMENT; REMARKS.

(Under the care of Dr. HUNTER MACKENZIE.)

CASE I. *Case of Syphilitic Ulceration of the Pharynx; dysphagia; rapid improvement under local and constitutional treatment.*—W. D—, aged fifty, married, labourer, applied to Dr. MacBride on the 18th April, 1880, and by him was transferred to Dr. Mackenzie. He complained of difficulty in swallowing, regurgitation of food through the nose, shooting pains in the ears, and general weakness. These had existed for about two months, but had become worse during the last two or three weeks. He acknowledged having had a chancre, followed by a bubo, when about twenty years of age, but never before had sore-throat. Now temperate, but at one time drank freely. Had had various manifestations of tertiary syphilis, and his wife had three miscarriages.

On examination patient was thin and sallow, scalp extensively studded with cicatricial marks, hair sparse and dry. Temperature 98°8', pulse 82. He had no difficulty in respiration, but there was great dysphagia, and he could only swallow fluids in small quantities. The tongue was furred, but not fissured. The retro-pharyngeal wall was deeply excavated, and covered with a foul slough, the ulceration extending transversely over the whole breadth of the wall, and vertically from the naso-pharynx to the epiglottic line. At the lower part was a peninsula of flabby granulation tissue, running into the sloughy mass, and resembling a new growth. There was an absence of cervical glandular enlargement. On laryngoscopic examination the veins at the base of the tongue were seen enlarged, the free edge of the epiglottis was serrated from old ulceration, and the ventricular bands were swollen, and overlapped the vocal cords to about one-third of their extent. The posterior nares were congested, not ulcerated.

The case was treated locally by free and frequent applications of an alkaline spray to the ulcerated surface, which cleared away quantities of the slough, and prepared the parts for the application of solutions of nitrate of silver, 90–240 grains to one ounce. Internally he was ordered the iodide of potassium, fifteen grains, thrice daily, before food, together with mercurial inunction each evening after the ulceration had ceased to spread. Under this treatment he made rapid improvement, and on May 2nd he reported himself feeling as well as ever, with no difficulty in swallowing even solid food. The headaches and attacks of giddiness from which he formerly suffered had also abated, and the ulcerated surface was quickly healing up. At his own desire he discontinued attendance on May 30th, feeling now extremely well, and having resumed work. He was, however, warned that the disease would most likely recur, the time during which he had been under treatment having been too short to produce a permanent cure.

CASE 2. *Case of Pulmonary Phthisis, with Laryngitis; paresis of, and papillomatous growth on, left vocal cord; improvement under constitutional and local treatment.*—Mrs. M—, aged thirty-six, was sent to Dr. Mackenzie by Dr. Carmichael of Northumberland-street, on March 22nd, 1880. She complained of hoarseness, difficult and noisy respiration, cough, and weakness. Never very strong, but had no hereditary tendency to phthisis. Had a severe attack of acute laryngitis in October, 1879, from which she never wholly recovered. Thenceforth she had been subject to severe sweatings, and had also got thinner. Dr. Lumgair of Largo, by whom she was treated during her acute laryngeal attack, reported that he suspected a syphilitic taint in the constitution of the patient.

On examination patient was thin and nervous; pulse 93, small; temperature 99°8'. There was marked inspiratory

strider, and the phonation was husky and broken. There was no pain, tenderness on pressure, or swelling in the laryngeal region. On laryngoscopic examination the fauces were pale, not irritable; the left vocal cord was entirely obscured by the swollen ventricular band on the same side, and a small papillomatous growth, evidently attached to the left vocal cord towards the posterior commissure, projected into the glottis. The left arytenoid cartilage and ary-epiglottic fold were swollen, and a similar swelling, but less in degree, existed on the other side. The epiglottis was free from swelling and there was no ulceration. On phonation, the left vocal cord was apparently immobile, and maintained the cadaveric position, whilst the right crossed the median line, so as to make up, as far as possible, for the defective movement of its fellow. There was slight comparative dulness at the right pulmonary apex anteriorly, with bronchial breathing; respiration jerky at left apex.

The treatment of the case was—(1) constitutional, consisting of the administration of one drachm of the syrup of the iodide of iron, with five grains of iodide of potassium, thrice daily (the patient was unable to take cod-liver oil in any form), and (2) local, embracing the occasional application to the larynx of a solution of perchloride of iron, one hundred and twenty grains to an ounce. To these was subsequently added (3) the continuous inhalation of undiluted creosote by means of a respirator specially constructed for the purpose.

Under this treatment the patient made good progress both as regards the general health and the local condition. This was shown by increase in weight, falling of temperature and pulse, and abatement in the amount of inspiratory stridor. On the 15th June the laryngoscopic appearances were far from healthy, but the partial subsidence of the tumefaction, and less prominence of the growth, were an improvement on what formerly existed, and contributed proportionately to the ease and comfort of the patient. The greatest benefit seemed to follow the creosote inhalations.

Remarks by Dr. MACKENZIE.—This case might be classed by some as one of laryngeal phthisis, but I have preferred to describe it as an instance of simple laryngitis on account of the absence of certain of the usual manifestations of phthisis of the larynx. The swelling of the arytenoid cartilages and ary-epiglottic folds, whilst resembling in its contour the pear-shaped tumefaction of phthisis, had not the peculiar ashy-grey opaqueness which characterises the last-named condition. The absence of irritability and pain, and normal condition of the epiglottis, which in the second stage (tumefaction) of laryngeal phthisis generally participates in the swelling, are also in favour of simple laryngitis. The paresis of the left vocal cord seemed to be peripheral and mechanical in character, from the inflammatory swelling interfering with the natural mobility of the parts; at least, no trace of any glandular or other enlargement could be detected in the course of the recurrent laryngeal nerves. In the inflammatory attack we have the origin of the papilloma, which generally arises in this way. The syphilitic taint alluded to in the history of the case was not manifested in the laryngeal affection, although Dr. De Havilland Hall has lately (THE LANCET, 12th June, 1880) recorded a case of syphilitic laryngitis, which yielded readily to treatment, where the appearances resembled those usually met with in laryngeal phthisis, but in which there was no lung affection.

Although the case in its laryngeal manifestations seems at the present time to be of a simple inflammatory nature, it is quite possible that it may eventually develop into phthisis, more especially as the lungs have already commenced to undergo the phthisical process.

GENERAL HOSPITAL, SHANGHAI.

PERITONEAL ADHESIONS IN TROPICAL ABSCESS OF THE LIVER; DEATH; REMARKS.

(Under the care of Dr. EDWARD HENDERSON.)

A Russian sailor was admitted on March 20th last. He was a well-developed man of about thirty years of age, thin, but not emaciated, and very anæmic. He appeared to be dying. His illness, it was stated, had lasted about six weeks; it had been characterised by fever of an uncertain type; latterly he had suffered from pain in the region of the liver, which had gradually increased. Physical examination was necessarily imperfect, but it was ascertained that the tissues of the back, legs, and thighs were dropsical, and that

there was fluid in the abdominal cavity. In the right nipple line there was nearly absolute dulness from the fourth rib downwards to a point three inches below the ribs—about eight inches in all. On the right side and in front over the liver the intercostal spaces were on a level with the ribs, and there was diffuse tenderness over this area. The urine was examined and found free from albumen. A mixture containing tincture of digitalis and compound spirit of ether was given, along with such suitable nourishment as the patient could take. On the following day he had rallied somewhat, and lay on his right side. The pulse could be felt at the wrist. The heart sounds were very feeble, but appeared to be normal; the apex beat could not be felt. No lengthened examination was at any time possible, but the diagnosis was in favour of hepatic abscess. On the 23rd it was deemed useless to delay operative interference longer, and it was decided to open the abscess by antiseptic incision, if the aspirator confirmed the diagnosis. Before deciding absolutely in favour of this method of operating, search was made for friction-sounds indicating peritonitis, and the probable presence of adhesions. Coarse friction was distinctly heard at one point below the margin of the ribs. Ether was administered, but after a few inhalations, insufficient to produce anaesthesia, the patient stopped breathing, and his pupils dilated widely. Artificial respiration was tried, and the tongue drawn forward, with the effect of again restoring the respiratory movements and a naturally-contracted pupil. This improvement was, however, of short duration, and the patient died. Immediately after death the large needle of Mathieu's aspirator was introduced below the ribs in the right nipple line, and, at a depth of about an inch, pus flowed into the receiver. The needle was then withdrawn. The body was examined on the following day.

On opening the abdomen pus was found lying on the surface of the right lobe of the liver in the meshes of a few adhesions, which were easily swept away by the finger. The puncture made after death came at once into view, pus issuing from it in a small continuous stream. At the back, below the coronary ligament and in a line with it, there were other adhesions, but these also were slight, and apparently recent. There were no other abnormal adhesions between the liver and its surroundings. The right lobe of the liver was the seat of an abscess as large as a man's head. Above and in front the walls of this abscess were formed only by a layer of fibrous tissue and the capsule; below there were about two inches of the secreting structure of the gland left. Clear serous fluid was found in considerable quantity in the cavities of the peritoneum, pleuræ, and pericardium.

Remarks by Dr. HENDERSON.—With so large an abscess, and so near an approach of pus to the surface, considerable and firm peritoneal adhesions might reasonably have been expected; their absence is a point worth noting, especially at a time when free antiseptic incision seems likely to become the recognised mode of dealing with the disease. The formation of adhesions is diagnosed by the occurrence of acute localised pain, and by the friction-sounds which at one time or other can be heard over the painful area. The immobility of the liver during the respiratory movements suggests itself as a further test, but I have myself had no practical experience of its usefulness. In the case just given the history of acute pain was absent, and friction was but once heard. In doubtful cases, when it is proposed to open the abscess below the ribs, it would be well to expose the surface of the liver by an incision sufficiently large to admit the finger; through such an opening the presence or absence of sufficient adhesions might be determined, and the subsequent steps of the operation arranged accordingly.

Such cases as the one under discussion are of course now rarely met with, but I have preserved the notes of a nearly parallel example which I saw at Shanghai in the autumn of 1869. At that time it was thought right by many practitioners to wait before opening an abscess in the liver until distinct bulging with œdema of the subcutaneous tissue indicated the near approach of the matter to the surface of the body. Some cases were, I believe, lost in this way, which, under more active treatment, might have been saved; but it cannot be denied that at that time the results of anything like early interference were most discouraging. The case to which I specially refer now was under observation in Shanghai for twenty-eight days, during which

time two proposals to open the abscess with a trocar were negatived in consultation. The patient died before the abscess showed any sign of pointing; and at the post-mortem examination, although an enormous abscess was found occupying the right lobe of the liver, and closely approaching the surface of the gland over a wide area, yet only a few inconsiderable and apparently recent adhesions were seen in the right infra-axillary region. I can well remember how triumphantly this was recognised as a proof of the folly of surgical interference in such a case.

In January of 1875 I saw a case in consultation which further illustrates the point. I regarded it as peculiarly favourable for operation. The patient, a young male adult, had been ill for ten days, during which time he had suffered considerably from pain in the region of the liver. When I visited him he was in bed resting on his right elbow, in a half prone position, to "ease the pain" he said. His general health had not then suffered seriously. The liver dulness was considerably increased, and the intercostal depressions were nearly obliterated on the right side, and in front below the fifth rib. There was a rounded prominence in the epigastrium, in which obscure fluctuation could be felt; this tumour was absolutely dull to percussion, and its dulness was continuous with that of the liver. The stethoscope was not used. The No. 2 needle of a Dieulafoy's aspirator, dipped in carbolic acid, was introduced into the centre of the swelling, and about two ounces of pus were drawn off. Two more operations at which I was present were done in the same way, as nearly as possible in the same place, and with much the same result. Ten days after the first operation the patient died rather suddenly, the abscess having burst into the peritoneal cavity. I witnessed the post-mortem examination. The abscess had given way posteriorly. There were no adhesions in front where the aspirator had been used, and the needle punctures were apparently closed.

At a post-mortem examination made in the Shanghai General Hospital in July, 1874, I saw a liver removed from the body of a male adult which contained, in a large cavity centrally situated, nearly three pounds of pus. In this case there was a complete absence of adhesions. During the four days the patient was in the hospital he complained of no pain or tenderness in the region of the liver; he was then, of course, dying, but was quite sensible and able to answer questions.

Even when the aspirator is alone used there is risk, unless the surface of the liver is sufficiently adherent to the parietes. An acute abscess of the liver cannot be emptied through the small needles supplied with aspirators, the fine channels of these being invariably blocked by the shreds of necrosed tissue to which the pus from such an abscess always contains. On the other hand, the large needles, through which alone evacuation can be effected, leave a wound by which the pus may easily find its way into the peritoneal cavity if the surface of the liver is still free. In the autumn of 1877 a death occurred in my own practice apparently in this way. My patient, a female, had dysentery. My first visit was paid on Oct. 8th. On the 14th a liver abscess was diagnosed, and she had acute pain and much tenderness in the liver area. On the 19th I punctured the abscess in the right hypochondrium, immediately below the ribs, with the large needle of a Dieulafoy's aspirator, repeating the operation on the 22nd. The presence of sufficient adhesions was inferred in this case from the character and duration of the pain, but the stethoscope was not used. She died on the 27th from general peritonitis. At the post-mortem pus was found lying between the abdominal parietes and the surface of the liver, in communication with the pus in the abscess. There were many recent adhesions between the liver and the surrounding parts. A little longer delay in operating in this case might have secured a favourable result.

It must not be supposed from the foregoing that I would for a moment council any return to the expectant treatment of hepatic abscess, the fatal results of what I have too often witnessed in former years. I am now only anxious to point out the necessity there is for care in operating, and to show how much may depend on the careful and intelligent observation of a case from day to day during its whole progress.

THE NEW HERTS CONVALESCENT HOME will be opened at St. Leonards on October 21st by the Princess Christian. About £1500 is still needed to meet the cost of the new building.

Reviews and Notices of Books.

The Riviera. By EDWARD I. SPARKS, M.A., B.M. Oxon. London: J. & A. Churchill. 1879.

IT is a fashion, and undoubtedly a good fashion, of the present day to send patients suffering from consumption and other constitutional chronic maladies to climates which may enable them to throw off their ailments. To wrongly advise a patient in such a matter means very often the mere emptying of his pocket for the benefit of the hotel-keeper and the undertaker; while sound advice, advice based upon real knowledge, will often prolong the existence of lives which are of inestimable value. The climate which will do harm or good is often extremely localised. The sending of a patient to the wrong town of a district, to the wrong part of a town which may have been judiciously selected, to a wrong hotel, or even to a wrong room in a well-selected hotel, may cause the best laid schemes and the kindest intentions to work mischief rather than benefit. In arriving at conclusions on such matters we must trust entirely to the information of those who live on the spot, and it is admitted that disinterested observers who are actuated by a purely scientific spirit are few and far between. On this account Dr. Sparks' book will be very welcome to the profession at large, for every chapter of it shows that it is the work of a man of learning and science.

The first chapter, on the meteorology of the Riviera, furnishes many important facts. The mean difference of temperature between sunshine and shade, during the winter months, is 73° F., and thus the risk of chill in passing from sunshine (averaging 129° F.) to shade (averaging 56° F.) is always very great. The mean winter temperature of the district appears to be from eight to ten degrees higher than that of London, the difference being least in the months of December and February. On the shortest day of the year (Dec. 21st) the sun is above the horizon in the Riviera for 8 hours 43½ minutes, as against 7 hours 40 minutes in England, and all through the winter months the Riviera day is slightly the longer. The main cause of the difference in temperature of different parts of the Riviera is the varying amount of protection afforded by the range of the Maritime Alps. Where the mountains approach the coast the snow-chilled winds from the Alps blow more or less completely over the towns nestling at the mountain-base. This is the case at the western end of the Riviera. Where, however, as at Genoa, plains intervene between the snow peaks and the town, the cold current from the north blows without let or hindrance. At Genoa the annual rainfall is 1317 mm., and there are sixty-seven rainy days during the winter months, while at Hyères, at the extreme west of the Riviera, the rainfall is only 746 mm., and the number of rainy days in winter only thirty-seven and a half. The temperature of the sea along the Riviera is about 12° F. higher than the minimum temperature of the air. The mean winter temperature of the sea at Cannes is 57·2° F., as against 49·8° F. along the Cornish coast, and about 42° F. along the east coast of England. There is no doubt that the high temperature of the sea is one cause of the mildness of the Riviera climate. The amount of rainfall during the winter at Nice is much greater than in London, but the number of rainy days is very much less; while the number of cloudless days is about ninety-six at Nice, scattered equally throughout the winter months, to twelve in London, of which two occur in November, none in December, one in January, another in February, two in March, and the remaining six in April. The mean humidity of the air (saturation being 100) varies between 70 and 74 on the Riviera and between 83 (March) and 90 (January) in London. The rainfall in the Riviera is subtropical in character,

violent while it lasts, but rarely continuous for many days together. The visitors to the Riviera are constantly in dread of the north-west wind, the *mistral*, which has parted with its moisture in sweeping over Central France. Its advent is always accompanied by a fall of the barometer. "The mistral is more felt the further west you go, though it is by no means unknown as far east as San Remo." The south-east wind, the *scirocco*, is the wind that brings the rain. The north-east wind, or *greco*, is bitterly cold; this is the wind which makes the climate of Genoa so trying, and it blew there for part of the day on 309 days in the year 1872. The north wind, or *tramontana*, blows over those places which are immediately protected by high mountains, but it finds access to places situated at the extremities of long straight valleys like Vintimiglia. The sea-breeze is felt along the Riviera during the middle of the day, but at sunset the land-breeze immediately sets in. The sudden cold which occurs at sunset is well known, and might have been inferred from what has been said regarding the difference in temperature between sunshine and shade. Dr. Marcet's experiment upon one occasion showed that between 4.5 P.M. and 4.27 P.M., the time of sunset, the fall in the thermometer was 9° F.; at 4.40 it had risen again nearly one degree, and fell ten more degrees before midnight. Fog and mist are unknown along the Riviera, snow is a great rarity, and prolonged frost never occurs; 25.7° F. was the lowest temperature observed in Nice for twenty years. In forming an estimate of the climate of the Riviera, it seems to us to be very necessary to guard against the utterances of occasional visitors, who only pay short visits. While one fortunate visitor may tell with rapture of a Christmas like an English summer, open-air excursions, picnics, warmth and sunshine, another, less fortunate, may tell of everlasting mistral "iced winds" from the north, and other discomforts. It is well not to listen either to the optimist or pessimist. A reference to Dr. Sparks' book will tell exactly what the climate is. A man of sense will not expect to find a climate without some drawbacks, and will be thankful to know that, should he encounter bad weather in the Riviera, he has probably left something infinitely worse in London.

Chapter II., devoted to the trees of the Riviera, will prove of great interest to those who have to find amusement during an enforced sojourn in the district; it is full of information. Chapter III. treats of the medical aspect of the Riviera; and Chapter IV. is devoted to a consideration of the journey. The remaining chapters treat in more detail of the various health-resorts along the Riviera, and in them will be found much indispensable information concerning Hyères, Cannes, Nice, Mentone, Bordighera, San Remo, Alassio, Pegli, Cornigliano, Nervi, Rapallo, and Spezia. These chapters show, among other things, how worthless are the utterances of interested persons as regards climate, and how easily an "authority" with local bias may blind himself to the shortcomings of the spot which he has selected as his professional habitat. To judge of a health-resort one must know it personally, unless able to refer to an honest book like that which Dr. Sparks has written. In the next edition we hope to see introduced a good map of the district and plans of the various towns. This would increase the value of the work immensely. As it is, we can most cordially recommend the work to our readers as one of exceptional worth.

On Deafness, Giddiness, and Noises in the Head. By EDWARD WOAKES, M.D. Lond., Senior Surgeon, and Surgeon to the Ear Department, at the Hospital for Diseases of the Throat and Chest. Second Edition. London: H. K. Lewis. 1880.

THE early demand for a fresh edition of Dr. Woakes' little volume is a sufficient criticism of its merits. Barely an interval of eighteen months has elapsed since the publication of the first edition. This circumstance becomes the more significant when considered in conjunction with the fact that

the work is rather a dissertation on some speculative points in aural pathology than a manual on diseases of the ear. In the preface to the first edition the author described his point of departure, and in the preface to the second edition he states that he has attempted to extend still further the lines on which he originally started. From considering the association of neuralgia with herpes, and the analogous phenomena attending wounds of nerves, Dr. Woakes was led to observe the nutritive correlation of regions and parts, otherwise unconnected, through the intermedium of vaso-motor innervation. In consequence of this relation any departure in any one region from its ordinary state is immediately appreciated by a corresponding set of nutritive changes in the other. The explanation of this mutual interdependence between the respective regions is, he thinks, to be found in the association of their afferent and efferent nerves with a given sympathetic ganglion, and in this way certain physiological and pathological processes in the ear, as well as tinnitus and vertigo, are investigated and explained.

The method which Dr. Woakes has followed in attempting to elucidate some of the more intricate problems in aural pathology has enabled him to lift the subject out of the low depths of narrow, and too often ignorant, specialism to the higher platform of scientific inquiry. Though Dr. Woakes' inferences may not all be equally conclusive they are always ingenious, and extremely plausible. His explanation of the association of inflammation of the inner and middle parts of the ear with dentitional derangements in infants is at once sensible and suggestive. The amount of preventable deafness due to neglected or despised inflammations during infancy and childhood is a sad reflection on medical practice. It would be no exaggeration to say that, of all cases of deafness, at least 70 per cent. are due to purely preventable or curable causes. The following is a good illustration of the way in which severe inflammation of the ear is often overlooked. An infant that is teething shows evident signs of acute suffering in its troubled face; it cries or shrieks piteously whenever its position is changed, especially if this be done suddenly, and it constantly raises its hand to its head. "Now, the point which I wish to emphasise is this," says Dr. Woakes. "The pain thus experienced is not what we vaguely call neuralgia; it is a definite trophic change, an inflammation taking place in the deeper-seated tissues of the ear, beginning with congestion and stretching of an acutely sensitive region, passing on to exudation and suppuration, capable of being recognised if the proper means are used for doing this." Often, however, the case is not seen till late, and the child either dies from an extension of the inflammatory processes to the brain or its membranes; or a sudden subsidence of the acute symptoms takes place, accompanied by a discharge from the ear. No more is thought of the affair, except, perhaps, to congratulate the parents on the existence of such a "useful derivative" as a copious discharge from the ear, which it would be folly to attempt to arrest. Meanwhile, the middle ear of the patient is undergoing suppurative inflammation; its delicate textures are breaking down, and soon irreparable mischief will be accomplished. This, we can affirm with the author, is no fancy portrait, but has occurred thousands of times, is occurring almost daily, and will continue to occur unless means be taken to recognise the true nature of the symptoms, and to treat them appropriately.

We cannot dwell on Dr. Woakes' explanation of deafness in adults arising from paresis of the palato-tubal muscles, nor on his ingenious speculations on ear-cough, ear-sneezing, vertigo, and noises in the head. No brief summary of his views could do full justice to the cogency and subtlety of his reasons. We prefer to commend the whole work to the thoughtful perusal of all intelligent medical practitioners who desire to rise above the level of mere routine empiricism.

THE LANCET.

LONDON: SATURDAY, AUGUST 28, 1880.

THE current number (August) of the *Contemporary Review* contains, among much interesting matter, a suggestive article, by Dr. KARL HILLEBRAND, on "Half Culture in Germany," in which "even Englishmen may find something to interest them." Our object in referring to this article is not so much to call attention to the state of education either in Germany or in England, as to give what emphasis we can to some of the principles which Dr. HILLEBRAND indicates. These principles are both logical and rational, and are, we believe, the only ones on which the methods of true education should be based. Of late years there has been a growing tendency to eliminate from general preliminary education everything that is not likely to be directly useful in a boy's subsequent career. The classical languages are the especial bugbear of so-called educational reformers, and it is proposed that natural science should be put into their place. The dictum is constantly dinned into our ears that chemistry, physics, botany, and biology are the well-springs of all intellectual and moral vigour, and examinations the final test of capability. Mnemonical accumulation of facts is the modern equivalent of culture, and stringency of examination is regarded as the measure of attainments.

It is gratifying to find an authority of Dr. HILLEBRAND's pretension taking a decided stand against these modern views. "Culture," he says, "does not mean a vast quantity of knowledge—on the contrary, it demands a wise restriction." There will, he goes on to state, always be some matters which we must ignore in order to be able to live at all, such as dirt in the physical, misery in the emotional, and technical knowledge in the intellectual world. As the cleanest of the clean must eat his bread and drink his wine without inquiring too curiously how they were made and who has handled them, and as the most compassionate person can hardly expect to protect the whole animal kingdom from suffering and persecution, so even the most learned among the learned will scarcely be so ambitious as to wish to master every branch of science. "In life itself," says Dr. HILLEBRAND, "we are obliged to restrict ourselves to what lies nearest to us, and the true purpose of the school is not to anticipate the lessons of life, but so to discipline the mind that it may be prepared to learn them from experience. Far too much is taught—nay, too much is read." This is, we fear, precisely the condition which is the bane alike of preliminary and professional education: "too much is taught—nay, too much is read." Anyone looking over the prospectuses of the various medical schools for the first time would be appalled by the number and complexity of subjects comprised within the medical student's curriculum. It requires actual experience to prove how chimerical all this outward show is, how valueless, how false! There is in it

nothing of training, and certainly nothing approaching to culture. Observation of facts merely as such is glorified to the exclusion of all exercise of reasoning, reflection, and judgment. The larger the number of facts that can be crowded into the student's gaze, the greater is the educational value supposed to be. But this is true only within very narrow and circumscribed limits. There soon arrives a stage at which numbers become confusing, and observation meaningless routine. Intellectual knowledge is individual and subjective—that is to say, unteachable. Experience alone can teach what life contains, and the schools can but train the organs which grasp that experience.

As to the relative merits of liberal education and professional education, Dr. HILLEBRAND maintains that when once a sound general education has been given, special knowledge is easily acquired in the technical schools. No early professional training can supply the place of a liberal education. He condemns as "false the opinion that the time is lost which is spent in learning things that do not bring any immediate profit," and maintains that it is much more advantageous to enter life with a completely formed and disciplined mind—that is, with a perfect instrument—than with a quantity of special knowledge.

Dr. HILLEBRAND's opinion of the relative value of the modern languages and a thorough study of mechanics and the natural sciences on the one hand, and the classical languages and mathematics on the other, as a means of general education, is very decidedly in favour of the latter. "Whoever considers," he says, "the matter, even superficially, will come to the *a priori* conviction that language, which is at once thought and the form of thought, while at the same time it is the symbol of all feelings, sensations, and things, must be a more important means of mental discipline than any other manifestation of the human mind, if only because it is the most general and comprehensive of all; that which embraces most of what goes on within us, which brings most clearly to our consciousness what happens around, which conveys most distinctly the communications between man and man." But the educational value of ancient languages does not lie merely in the literature to which they are the key; it is essentially formal. "Thus, Latin grammar is a course of logic presented in an almost tangible form. Greek, on the other hand, I might," he adds, "almost call a course of æsthetics, by means of which we learn to distinguish a thousand gradations of meaning which our barbarous languages will not allow us to accentuate." In short, Dr. HILLEBRAND sees in classical study not only the most effectual corrective to the atomical tendencies of our age, "which threaten, unless resisted, to reduce us to the condition of disconnected grains of sand"; but also the most admirable of mental gymnastics, "which, when applied by even the dullest and most awkward mind, renders it bright, pliant, and strong—the school of logical thought, of intuitive perception, and of just judgment." If this estimate be true, it must be allowed that the legislation and regulations for the preliminary and professional education of medical students have for a long time been in an entirely wrong direction. Those who have the charge of the preliminary training of intending medical students will do well to consider whether a liberal education such as

Dr. HILLEBRAND recommends will not also be the best equipment for a medical man.

THE mode of formation of callus is a subject of both practical and pathological interest. In the year 1865 M. RANVIER showed that the callus which is formed in simple fractures, in men and animals alike, passes through a cartilaginous stage, while in compound fractures there is no cartilaginous stage; new bone is at once formed from granulations which come from the medulla of the fractured bone. He showed also that suppurative inflammation does not interfere with the formation of bone in cartilaginous callus, when the latter has once been formed. These researches left still undecided the question of the cause of the difference in the process under the two conditions. This point has been further studied in an investigation described to the Académie des Sciences by two pupils of M. RANVIER, MM. RIGAL and VIGNAL. They find that (1) even in simple fractures the central plug always becomes directly bony in the middle of the medulla, which has assumed an embryonal structure. (2) When a part of the bone is scraped away, either down to the medullary canal or less deeply, the cicatrix is always directly bony, even when union is by the first intention, a fact also observed by M. RANVIER. (3) In a compound fracture, even if the fragments of bone are left exposed to the air for a considerable time, if suppurative inflammation can be avoided, and union by the first intention thus obtained, the callus passes through a cartilaginous stage. (4) That in a compound and suppurating fracture the callus is at first cartilaginous in the points not invaded by the suppuration, while even in simple fractures, in which the extremities of the bones are, from any cause, bathed in pus, the callus is still primarily bony. These different facts led the investigators to conclude that if in compound fractures the callus is primarily bony, it is because the periosteum, or more exactly the subperiosteal layer of cellular tissue, was destroyed by the suppuration; and they have arrived at the conclusion that this layer alone is concerned in the formation of cartilage, and that the medulla of both the Haversian canals and of the central canal forms bone directly. Several attempts were made to obtain bony tissue from medulla transplanted into the subcutaneous cellular tissue, but all failed, while subperiosteal tissue thus transplanted invariably produced bone which was at first cartilaginous, as M. OLLIER had already found. From the lower third of the tibia of a rabbit the periosteum was removed three or four times, so as to destroy all its osteogenic properties. Then, fifteen days after the last removal, the bone was broken in the middle of the denuded portion. Twelve days later, a period at which, in the rabbit, a cartilaginous callus is usually found, the animal was killed, and the examination of the fracture showed that in the midst of granulations proceeding from enlarged Haversian canals, there was a peripheral callus, purely bony. The experiment was repeated several times with the same result. A still more conclusive experiment was the one in which the periosteum was removed from one surface only, and the bone then broken. Upon that surface the osseous callus formed directly, as in the case of compound fractures, while upon the surface on which the periosteum was preserved the callus was car-

tilaginous. These experiments show that the subperiosteal layer, when there is active irritation, as in the case of fractures, contributes to reparation by forming cartilage. But there are numerous cases in which the subperiosteal tissue forms bone directly, and experimentally it could be made to form bone or cartilage at will; with slight irritation bone is formed, with greater irritation cartilage. In the same animal the periosteum was exposed on both legs; on one it was irritated gently by rubbing (as with an agate burnisher), and in the other leg it was irritated strongly, and the adjacent soft parts were bruised, so as to cause an extravasation. If union of the wounds by first intention was obtained, in the former osteophytes were found beneath the periosteum on the twelfth day, while in the latter there were only cartilaginous masses. The latter experiment explains the direct formation of bone at the points of the callus which are farthest from the fracture. In the experimental fractures it was invariably found that in the extremities of the oval mass of callus, bone was formed at once—the inflammation at these points being less active, the subperiosteal cellular layer formed bone immediately.

IN another column we print a letter from Dr. ROBERT BARNES, directing attention to certain practical aspects of the Guy's case which are in danger of being overlooked. The excuse pleaded by the nurse when before the Treasurer, as recited by Dr. PAVY in his letter of last week—namely, "that she had been given to understand that the patient was suffering from hysteria, and that she thought she was only putting in force the proper treatment,"—rests on three assumptions: "(1) That hysteria is a disorder rather moral than physical; (2) that, therefore, hysteria may properly be treated on penal principles; (3rd) that a nurse is competent, of her own motion, to apply that treatment." These are, as Dr. BARNES points out, very grave propositions. The first is simply absurd; the second mischievous; the third destructive of the first and last principles of medical practice.

It would be difficult to expose the misconception as to "hysteria" which seems to prevail in certain—even professional—circles more tersely or clearly than Dr. BARNES has exposed it. "Wherever the phenomena known as hysteria present themselves, there is surely underlying them as cause a pathological condition which it is the business of the physician to discover and to treat. To treat hysteria medically is to treat a symptom—a course sometimes judicious, but hardly scientific. To treat hysteria penally is, in plain language, to treat the patient brutally. Hysteria is no more an independent disease than is neuralgia, chorea, epilepsy, or other covert manifestation of disease or disorder of the nerve-centres. As well might we apply penal treatment to these nervous phenomena as to hysteria. The penal treatment of hysteria is a remnant of the barbarous era of medicine, when lunatics were so treated." This is a simple and forcible statement of facts. Cases of "hysteria," "neuralgia," "epilepsy," and the like, are on a footing with cases of ill-temper or passion, pain, fidgets, formulated or organised nerve-disturbance. They are not diseases, but states; and the troubles to which for convenience Art gives a name are known to Science only as the symptoms or expressions of a pathological condition which it is the duty of the physician to explore. We shall never be wholly

rid of the perils and contingencies of treatment for these pseudo-diseases until the practice of considering and describing effects as causes is abandoned.

Meanwhile it is necessary to observe that the line of reasoning adopted is not wholly faultless. The syllogism of the defence, as Dr. BARNES would hypothecate it, stands thus: Moral diseases require moral treatment (which is true in itself). 2. Hysteria is a moral disease (which is false, because hysteria is not a disease, and if it were it would not be moral). 3. Therefore hysteria requires moral treatment. The first proposition is accurate in the abstract, but its application is very limited because it is difficult to name more than one or two diseases which are even *supposed* to be moral. "Moral insanity" is the chief of these, and the tendency of scientific inquiry points to the conclusion that before many years this term will be eliminated from the nosology of mental disease. Every step onwards makes it increasingly evident that even the more purely mental phenomena are the expressions of a force acting exclusively through, and limited by, if not arising within, the physical area. Even though it be possible, as it clearly is, to operate upon the brain as an organ through the mental faculties which are its functions, and so to re-educate it, or improve its development reflexly, the fundamental principle of this method of treatment lies in the recognition that the phenomena of disorderly brain and nerve action are not diseases, although they proceed from pathological conditions. This much must be conceded. It is, however, necessary to point out that although the symptoms of a pathological condition do not constitute a disease, it may be necessary to treat the disease through the "symptoms," that being the only way to approach it. An illustration of this method is that to which we have alluded, the development of the brain by re-education. It would not, therefore, go without saying that because hysteria is not a moral disease—or a disease at all—it could not require moral treatment! The treatment of "symptoms" is sometimes the only possible mode of treatment, and in respect to *all* developmental diseases where the morbid condition is chiefly one of function, a large part of the treatment must be functional. The treatment of an atrophied and paralysed muscle is by exercise—that is function—and in so far as conduct is the outcome of brain action, conduct must be made the medium of brain treatment on the same principle that a muscle is first moved passively, and then stimulated by electricity to promote its nutrition and restore its normal state. We do not allude to this imperfection in the argument with a view to weaken it, but the rather to clear the line of reasoning of a possible obstruction.

It is plainly wrong to class hysteria as a disease, and there is not a particle of evidence which could even be pressed into service as an excuse for regarding it as a moral affection. To treat it penally is, as Dr. BARNES justly insists, "to treat the patient brutally." If it were otherwise, as the law at present stands, the moral treatment required would be out of place in an hospital. The use of the bath as a punitive measure has been long interdicted in the practice of establishments for the insane; it would be strange indeed if it were revived in hospitals. The main point, however, is the system and principle of *treatment by nurses or sisters*. This is a most serious evil, and one which cannot be too strongly denounced. Nothing should be left

to a nurse, whether it be the use of a bath at discretion, or the exercise of judgment as to the expediency of getting a patient out of bed. The physician's directions ought to be precise, and it is by failing to give definite instructions, and leaving details to nurses, that the growth of nursing into a separate system has been encouraged. A strong and clear bearing at the outset would have prevented the rise of this hydra-headed evil. Nothing can explain the omission to make every detail of hospital management a part of "treatment," except the neglect to recognise the fact that a hospital is something more than a home where sick persons happen to live, and in truth a medical establishment for the cure of disease; or the existence of a trouble-saving policy which seeks relief from the pressure of hospital work in leaving as much as possible to the nurses. Obviously no physician or surgeon can entertain the opinion that nursing ought to be something apart from, and independent of, the practice of the medical and surgical art. If any such notion prevail, let those who look on it with tolerance take warning from what has occurred in connexion with the asylums for the insane, where the relegation of moral and physical patients to attendants has led to the springing up of a class of officials who are more troublesome to manage than the patients, and who, when they are appointed by a house steward—the homologue of the hospital treasurer—are simply scorpions to the peace, and ceaseless enemies to the success, of asylum practitioners in lunacy. Regrets are vain. The up-starting of pretentious sisterhoods and pseudo-professional nurses has been permitted, if not encouraged. It only remains to exorcise the evil spirit which has been invoked. The sick poor are the sufferers by the new nursing system. Whatever inconvenience hospital physicians and surgeons may suffer must be patiently endured until it can be remedied. It is the penalty of the blunder which has been committed in dealing with the system of which it is the fruit. Meanwhile, in the interests alike of science and humanity, the assistance of the medical faculties of hospitals everywhere must be invoked to put an end to the nuisance and mischief of corps of nursing sisters and the "professed" who do not fulfil the qualification of being simply intelligent women content and modest enough to do what they are bid to do, in the way and at the time specified.

Annotations.

"Ne quid nimis."

CENSUS ENUMERATION IN THE UNITED STATES.

ALL interested in the science of vital statistics must be somewhat amused, if not incited to serious consideration by the local squabbling which is taking place in the United States with regard to the announced results of the Census enumeration now in progress. It is well known that there is much emulation among American municipalities as to the size of their respective cities, judged by the number of their population. It has, moreover, long been the conviction of most students of vital statistics that American mortality statistics are for the most part untrustworthy, not only from the defective system of death-registration which prevails in the United States, but also from the loose, not to say reckless, manner in which the population of its principal cities is estimated during the inter-census

periods. Let us take the city of St. Louis as an example. It has recently been semi-officially announced that the population of that city, at the Census just taken, does not exceed 375,000 persons, and that it may not exceed 350,000, when, as a local newspaper indignantly protests, "everybody knows that the population reaches or exceeds 500,000." The feeling which prompts this indignation is partially disclosed by what follows:—"How preposterous the official estimate of St. Louis is shown from the allowance of 475,000 to Chicago." We have before alluded in these columns to the incredible mortality statistics issued by the Health Department of the City of St. Louis, and attributed their fallacy mainly to an over-estimate of the population. We have before us the Condensed Statement of the mortality in that city during the year 1879. With regard to the population it is therein stated that it was 160,773 at the Census in 1860, and that according to the Government Census in 1870 it had increased to 310,864, "notwithstanding the depressing influences of the War." It is further intimated that by a recent enumeration in 1878 the population in 1879 was estimated at 503,000. The mortality statistics are calculated upon a round estimate of half a million; the result of which is that the 6167 deaths reported during the year give a rate of mortality equal to 12.33 per 1000. It is scarcely necessary to say that out of America no such low annual death-rate as 12 per 1000, in a large city, is ever heard of; and vital statisticians may be excused if they doubt the trustworthiness of such a death-rate. The death-rate in St. Louis during 1879 is, moreover, reported to show an increase upon a still lower rate in 1878. The continuance of so low a death-rate as 12 per 1000 in a stationary or life-table population would signify a mean duration of life of 83 years, while in England and Wales it does not exceed 40 years. We are able to calculate from the ages of the decedents in St. Louis, in 1879, that the mean age at death during that year was not quite 25½ years, and in no way approached the implied fourscore years. Making due allowance for the fact that the population of St. Louis, instead of being stationary, is a rapidly increasing one, it may pretty safely be estimated that the true death-rate of St. Louis is nearer 30 per 1000 than 12 per 1000. Convinced that the reported death-rate of 12 per 1000 is entirely fallacious, it is, even now that the new census numbers are beginning to be announced, exceedingly difficult to know how much this fallacy is due to an incomplete record of deaths, and how much to exaggerated estimates of the present population. It is said that the action of the Census Bureau is being severely criticised, on account of supposed serious imperfections in its enumeration. If, however, we may take the St. Louis case as a fair sample of the others, we have little hesitation in pronouncing the census number of from 350,000 to 375,000 far more worthy of trust than the 503,000 locally estimated from an enumeration in 1878. It may be hoped that the fallacy of so large a proportion of American mortality statistics, which will become the more patent when the new census figures are published, will direct renewed attention to the subject in the United States.

ADULTERATED BUTTERINE.

IN England we maintain the pleasing fiction that butter alone is allowed to be sold for food; but in France trade in imitation butter is openly carried on. M. Mège-Mouries is the author of a system for the manufacture of an economical fatty substance which is euphoniously termed "margarine butter." According to the original process the margarine, which may be found in most fatty substances, was extracted from fresh beef suet. When brought in contact with water containing a small quantity of carbonate of soda, and raised to a temperature of 40° C., the grease was liquefied and separated from all foreign bodies. It was then put under

hydraulic pressure in canvas sacking, which retained the stearine, while the oleine and the margarine were collected in the cylinders, and constituted a homogeneous paste, well suited to culinary purposes. This special description of butterine was sold in commerce as margarine, and when mixed with a little milk was known as margarine butter. For several years this substance found general favour. Families with restricted means and the small restaurant keepers found it a useful substitute for the butter they could ill afford to purchase; and had the matter rested there, no great complaint need have been made. The manufacturers thought, however, that this comparatively wholesome substance did not yield the large profits they desired. The precautions prescribed in the original process were neglected, the grease employed was derived from every source, and the result was anything but safe to the consumer. Ignoring this deterioration, it was recently suggested that margarine should be used instead of butter in the lunatic asylums of the department of the Seine; and the Ministry of the Interior consequently inquired officially from the Academy of Medicine whether it would be expedient to adopt this proposal. The question was submitted to M. Riche, of the Ecole de Pharmacie, and after various investigations this gentleman has replied that: "The primitive margarine has ceased to exist in commerce, and the margarine actually sold is an industrial product which lends itself readily to the practice of various frauds." Tallow from all sources, and at various stages of staleness, is freely used. Excessive pressure and the highest temperatures are employed in the process of manufacture, the better to disguise the abominable character of the fats; and so divergent are the means of production that it is impossible to establish or maintain any standard of quality. There is great danger that this latter-day margarine may be easily sold in consequence of the good reputation of the original margarine, though we have it on the high authority of M. Riche and the Academy of Medicine that the real substance has ceased to exist. It is to be feared also that the decisions and the labours of the Academy are not well enough known by the public at large to arrest the sale of spurious margarine. False butter is bad enough, but the adulteration of the already spurious article is a superlative degree of falsification which is not often taken into consideration, though but too often practised.

A MANUAL OF HYGIENE FOR INDIA.—PRIZE OF £100.

THE Government of India have offered a prize of £100 for the best Manual of Hygiene for the use of the British soldier in India. The work must be in clear and simple English, without theories, and thoroughly practical, showing the ordinary causes affecting health, the special dangers to health to which British soldiers are exposed in India, and more particularly during their first years in the country, and the best means by which these dangers may be averted. The work will, if accepted, be printed at the public expense, and become the property of the State. It must not cover more than fifty or sixty pages of print of small size. Competitors must send their manuscript addressed to the Secretary to the Government of India in the Military Department, Calcutta, so as to arrive there not later than the 31st March, 1881. The prize will be adjudicated by a committee, consisting of the Surgeon-General of Her Majesty's British Forces in India, the Sanitary Commissioner with the Government of India, and an officer of the Quartermaster-General's Department, to be appointed by His Excellency the Commander-in-Chief. The Government of India will not award the prize unless a manual is produced in all respects suitable for the purpose for which it is required.

Would it not have been well before this prize was offered

that the "Government of India" should have endeavoured to understand what a "theory" is, and particularly the distinction between a "theory" and a "hypothesis"? We can understand that the manual should be free from "hypotheses;" but how it is to be "without theories," if it is to be written in ordinary language, passes our comprehension. Moreover, what possible "manual" of hygiene can be written which will admit of being understood, and worth the paper it will be written upon, that is to be limited to fifty or sixty pages (assuming these to be of ordinary octavo size) even of small type? The capacity of the Government of India to commit follies in hygienic matters appears to be (and indeed must be, so long as it displays such astounding ignorance) inexhaustible.

THE PULMONARY VASO-MOTOR SYSTEM.

THE pulmonary branches of the pneumogastric nerve have, for a long time, been supposed to exert an influence on the contractile tissue of the pulmonary vessels. This opinion has, however, lately been contested by Brown-Séquard and Vulpian, who ascribed to the thoracic branches of the sympathetic the influence previously attributed to the pneumogastric. M. François Franck has been investigating the subject anew, and his results confirm the very conclusive experiments of Brown-Séquard. He has endeavoured to ascertain the vaso-constrictor action of the first thoracic ganglion upon the lungs by measuring the effect which stimulation of this ganglion exerts upon the circulation through the heart. If the vessels of the lungs contract, the pressure in the right side of the heart should be increased. Accordingly, it is found that when the nerves from the first thoracic ganglion are stimulated by an induced current of moderate intensity, for ten or twenty seconds, the pressure in the right ventricle gradually rises, remains high for about half a minute, and then slowly falls to the initial point. This result can hardly arise from any other cause than the contraction of the pulmonary vessels. If this be the cause, however, it should produce a corresponding fall in the pressure in the aortic blood, since the obstruction will hinder the passage of the blood to the left ventricle. The effect on the aortic system was estimated by measuring the blood-pressure at the central extremity of one carotid. The first effect was a slight rise, and this was followed by a considerable fall, which went on until the pressure in the right heart reached the normal point. The slight initial rise of pressure is an event which *à priori* reasoning would not have suggested. An explanation which M. Franck has given seems likely to be the correct one. The contraction of the vessels, which presents an obstacle to the action of the right heart, also expels an additional quantity of blood from the lungs into the left side of the heart, and the result is that the left ventricle, for a moment, sends an increased quantity of blood into the aorta, and this causes the transient rise of pressure. A very similar effect on the circulation may be produced by the compression of the vessels by excessive pressure of the air in the pulmonary vesicles. The effect on the right heart and venous system during severe coughing is, of course, familiar. M. Franck has reproduced it experimentally by inserting a tube into the trachea of a curarised dog, and then insufflating the lungs with considerable force. Lastly, the same phenomena occur as on faradisation of the sympathetic, including the initial rise in the pressure in the aortic system. The effect is produced equally well, whether the thorax is opened or closed—an important fact, since when the thoracic walls are intact some effect might be ascribed to the direct pressure upon the great vessels.

Another set of experiments were made to ascertain whether the pneumogastric nerves contain any fibres having an action on the pulmonary vessels. To learn this it was necessary first to eliminate the action of those nerves on the

heart itself. This was effected by placing the animal under the influence of atropine, which, as is well known, prevents stimulation of the cardiac extremity of these nerves from having any effect on the action of the heart. Under these conditions stimulation of the cervical part of the pneumogastric produced no action on the blood-pressure either on the right side of the heart or on the aortic system, which could suggest an action upon the vessels of the lungs. The experiments were repeated after the thorax had been opened, the colour of the lungs being observed, and at the same time the pressure on the pulmonary artery ascertained. Stimulation of the pneumogastric under these circumstances caused no pallor of the lungs, nor any increase of pressure on the pulmonary artery.

If, therefore, the vessels of the lungs can be made to contract by any reflex mechanism, as by irritation of the abdominal viscera, as has been asserted, the reflex action must be exerted through the sympathetic, and not through the pneumogastric nerves.

THE LATE MISS NEILSON.

DR. W. E. JOHNSTON, of the Boulevard Malesherbes, Paris, writes to *The Times* as follows:—"For the last five years I have had the charge of Miss Neilson's health during her visits to Paris, one of the treatments running through a period of four months. The disease from which she suffered principally was gastralgia—one of the forms of dyspepsia attended with neuralgia of the stomach, a form extremely fantastic in its coming and going, and in her case quite as dependent on moral causes as on errors of diet. The last fatal attack in the Bois de Boulogne was evidently one of her usual attacks of gastralgia, which might have been relieved then, as it often had been before, by a free use of morphine. The unfortunate lady sent her maid for me at seven o'clock, but to my great regret I was absent that evening on a visit to my family in the country, and did not hear of her illness till I heard of her death. At three o'clock in the morning, twelve hours from the commencement of the attack, during a most violent recurrence of the pain, she suddenly ceased to complain, went into a state of syncope, and died in the syncope. The post-mortem examination made the next day by Dr. Brouardel, Professor of Legal Medicine at the Medical School of Paris, and now one of the first authorities in Europe in legal medicine, disclosed the extraordinary fact, one of the rarest in the history of medicine, that in her writhing she had ruptured a varicose vein in the left Fallopian tube, and had died from internal hæmorrhage. Two quarts and a half of blood were found in the peritoneal cavity, and the ruptured vein presented an orifice of from four to five millimetres in diameter."

The following additional particulars of the fatal illness of the distinguished *artiste* will be read with interest:—Dr. Monnier, of 12, Rue Copernic, was sent for and arrived at four o'clock. He found great physiological disturbance and vesical irritation, pains in the back, and oppression of the chest with difficulty of breathing; pulse scarcely perceptible. He ordered tea; administered laudanum and ether, and gave instructions for linseed-meal poultices to be applied. The pain was not permanently relieved. Syncope occurred shortly afterwards, but the patient was restored by the application of warmth. Some time subsequently copious vomiting set in. About this time in the case a curious incident occurred, which somewhat disturbed the patient: a bat flew in at an open window and hovered around the bed. "Look at that great bird flying about me!" said Miss Neilson. After a while she grew quieter, and Dr. Monnier took his leave. Subsequently Dr. Gantillon was called in and ordered two pills (colocynth), which acted freely. At 3.30 Dr. Monnier received an intimation that the patient was

worse. On arrival at the house he found her apparently asleep, but was somewhat alarmed by her appearance. On returning to the room after a short absence, he discovered Miss Neilson had been dead about half-an-hour.

ENGLISH SURGERY IN JAPAN.

MR. C. J. MANNING, who left University College Hospital five years ago to undertake the duties of Surgeon to the General Hospital, Tokio Fu (Yeddo, Japan), and Lecturer in Surgery, is about to return to this country, his term of office having expired. We have received the following extract, a translation from the Japanese papers into the Yokohama English paper, which will show how well his services have been appreciated:—

“The term of service of Mr. Manning, of the Tokio Fu Hospital, having expired, the Governor of the Fu and the Superintendent of the Central Board of Health waited on the doctor at the hospital on the 1st instant, and gave him a certificate praising him for his skill and care in the management of the establishment, together with 350 dols. as a donation. Mr. Manning expressed himself pleased with the compliment thus paid him, and said the document would be valuable to him, but that he did not wish to accept the money, which he desired to be distributed amongst the poor of the Fu; it was accordingly handed over to the Fucho officers. Yesterday a grand entertainment was given to the doctor in the Seiyō Ken Restaurant.”

THE INFLUENCE OF PEROXIDE OF HYDROGEN ON FERMENTATION.

It has been shown by M. Paul Bert that oxygen at a high pressure destroys organised beings, and thus arrests all fermentations that are due to the growth of organisms, while it is without action upon the soluble ferments. It kills bacteria and microphytes, while it has no action on the salivary or pancreatic ferments. M. Regnard has instituted a series of experiments to ascertain whether substances which contain oxygen in a state of chemical tension—i.e., in a nascent condition—are capable of exerting the same influence. His first experiments, the results of which have been communicated to the Société de Biologie, have been made with peroxide of hydrogen. Some yeast was placed in two flasks containing a solution of glucose. To one was added a few drops of a solution of one cubic centimetre of peroxide of hydrogen in 100 grammes of ordinary water. To the other no addition was made. In the flask containing peroxide of hydrogen no fermentation took place, while in the other it proceeded rapidly. A quantity of common red wine was next taken, and divided into six parts. To three a few drops of peroxide of hydrogen were added, and the three others were left for comparison. At the end of a few days the latter were completely covered with mycoderms, while the others to which the peroxide of hydrogen had been added remained clear, and resembled in appearance that which had been exposed to compressed oxygen. If the quantity of peroxide of hydrogen was greater the wine became yellowish, and the colouring matter, oxygenated, fell to the bottom, the liquid acquiring an ethereal odour similar to that of sherry. Milk to which peroxide of hydrogen had been added, remained free from fermentation, and uncoagulated, at the end of a month. Two flasks were shown in which white of egg had been placed a month before. One had putrefied and stank horribly. To the other a few drops of peroxide of hydrogen had been added, and it was perfectly unchanged; urine and hydatid liquid behaved in precisely the same manner. On the other hand, the liquid was found to have no power to prevent the change of starch into glucose by saliva or pancreatic juice. The effect is thus exactly the same as that found by M. Bert with compressed oxygen.

The effect of the peroxide of hydrogen is not permanent.

If the oxygen is allowed to escape, putrefaction occurs. There are two possible theories regarding its mode of action. (1) The real action may be that of the nascent oxygen. (2) The effect may be due to its own molecular constitution. It is possible that, if the latter theory be true, compressed oxygen acts simply by forming, in the liquid exposed to its action, the peroxide of hydrogen, and M. Bert is inclined to accept this explanation of his researches.

These results are of interest, and deserve notice, but the influence of peroxide of hydrogen on fermentation is not a new discovery. Two years ago it was pointed out by Guttmann, and before him by Fraenkel (THE LANCET, 1878, vol. ii., p. 839). Of these observations M. Regnard seems to be unaware. The confirmation of previous research is important, but the case presents another instance of the ignorance of French scientists of that which goes on beyond the boundary of France, and which, as we lately remarked, renders so large a part of the scientific investigation in that country a series of rediscoveries of facts which have been already ascertained elsewhere.

TINNED FOOD.

LAST week we reported the poisoning, happily without fatal result, of a family at Barnsley from the ingestion of corned beef, which had been imported in the ordinary tin canister. We have since received authentic information of a case in which several members of a household suffered seriously after eating sardines preserved and vended in a similar enclosure. The father, who first partook of the fish, was affected but slightly, and failed to refer his ailment to what would appear to have been the real cause. Next day four of his children ate of the sardines from the same tin, and were attacked soon afterwards with severe vomiting, accompanied by considerable prostration. The other members of the family, who had not partaken of the sardines, experienced no disturbance of health. The facts seem to point to the tinned food as the source of mischief in this case, though whether the poison resided more immediately in the case, the solder which cemented it, or the fish itself, is not so evident. Meanwhile these recent instances suggest caution in the use of a description of food the consumption of which appears to be on the increase.

ANÆSTHETICS IN 1651.

IN a recent work, entitled “Histoire de la Médecine à Troyes,” Dr. Guichet relates that the College of Physicians of that town brought an action against a certain Nicolas Bailli for administering internal remedies to his patients and *putting them to sleep*. In defence Bailli declared that having observed that in great operations, amputations, incisions, actual and potential cauterisations, many patients slipped through his hands for want of sleep, he had studied the secrets of nature, and had at last found a cordial, or marvellous essence, which put them to sleep softly, and appeased their sensibility to pain.

DEATH OF SURGEON W. A. BURGESS, M.D., ARMY MEDICAL DEPARTMENT.

WE regret to announce the death, at Meerut, East Indies, on the 22nd July, of Surgeon William Armstrong Burgess, from the effects of a fall from his horse. Dr. Burgess entered the army as recently as September, 1875, and had nearly completed his first tour of Indian service.

POISONED HAM AND HERRINGS.

THE French police authorities have forbidden the sale of imported hams known in the trade as “Cincinnati.” The yellow material in which they are sewn is coloured with a chromate of lead. It is also said that they frequently

contain trichinæ. It has been found too that the golden hue, so appreciated by amateurs of "bloaters," is often imparted to them artificially by purveyors of this delicacy. Analysis has revealed here again the presence of one of the most toxic chromates.

THE Public Health Committee of the Corporation of Dublin have suggested in a recent report that, should a Convalescent Home be established, it be connected with Cork-street Fever Hospital; that a capitation fee for each inmate admitted from the city be paid by the Corporation; and that the funds collected for the erection of a Convalescent Home be transferred to the Governors of the Fever Hospital. The report has been adopted, with the exception of the clause pledging the Corporation to support a home at the hospital.

A SAD accident by which a member of our profession met with his death is reported in a local paper. Mr. H. J. Heywood, M.R.C.S., of Pendleton, to secure sleep whilst suffering from a painful malady had occasionally resorted to the use of chloral. The drug was, it appears, kept on the mantelpiece beside a bottle of prussic acid, which, one night last week, was taken in mistake for the hypnotic. The occurrence has created a feeling of general regret, and of profound sympathy with the bereaved members of the family of the deceased.

THE King's College Hospital "old students' dinner" is announced for October 1st, and will take place at the Inns of Court Hotel; Dr. Peter Eade, of Norwich, in the chair. It is to be hoped that the dinner will be as great a success as it was two years ago, when Professor Henry Smith acted as chairman, and that friends in the country will endeavour to be present. The honorary secretaries are—Mr. W. P. Goodall, Birmingham; Mr. Martin G. B. Oxley, Liverpool; Mr. H. Royes Bell, and Dr. Hayes, London.

THE French Minister of Public Instruction has named Dr. Mathias Duval, Professor agrégé of the Faculty of Medicine of Paris, to the posts of Director of the Laboratory and Professor at the School of Anthropology, vacant by the death of Paul Broca.

THE prize offered by Mr. V. F. Bennett-Stanford, of the value of £100, for the best essay on Hydrophobia, its nature, prevention and treatment, has been awarded to M. Bourrel, of Paris.

PROFESSOR GROSS, D.C.L., LL.D., &c., has been spending the past week in the Isle of Wight with Mr. Erichsen. He intended sailing for Philadelphia on the 25th inst.

THE physician of Lyons who endeavoured to emulate Dr. Tanner gave up the attempt after a week's trial.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

West Bromwich, Urban Sanitary District (area 5710 acres, population 53,609). Dr. Manley reports for 1879 a birth-rate of 42.6 per 1000 population, and a death-rate of 23.3. Infantile mortality was at the rate of 16.7 per 1000; and Dr. Manley holds, erroneously, as we think, that a high birth-rate means a high infantile death-rate. An epidemic of scarlet fever, the early severe weather, and the privations from bad trade, contributed to swell the mortality of the year. *West Bromwich* would appear to be in a transition

state in regard to sanitary matters, but the period of transition does not seem to be very clearly marked; and it is not quite clear that the change is beginning at the right end. Of the measures still required to be adopted in the district before "perfection" is attained, the Medical Officer of Health enumerates first the registration of infectious diseases, the provision of hospital accommodation for such diseases, and also of a mortuary and disinfecting chamber—all very necessary sanitary requirements if a sanitary authority is to do its duties effectually, but requirements we should be disposed to subordinate to the provision of the rudimentary conditions for the maintenance of health among a community. For it appears that even these are wanting in *West Bromwich*, as the medical officer of health enumerates among the further requirements of the place "public drainage" (only "now under consideration"), the "provision of pure water," "the prevention of building operations on insanitary sites," the regulation of new buildings, of the keeping of all kinds of animals, of lodging-houses, and of a local practice of cultivating damp in houses. We would reverse the order of his recommendations, putting those first which he gives last, and making those last which he gives first. Moreover, the death-rate from infectious disease, considerable though it may be, would not justify the sanitary authority in giving predominance to a particular method of treating them, above those general sanitary measures which are not only of the highest importance with reference to this one class of maladies, but are also of equal importance with reference to the other classes of disease which contribute to the mortality of the district.

PROPOSED SANITARY HOSPITAL AT PLYMOUTH.

Some time ago, under the combined pressure of a severe epidemic and the Local Government Board, the Town Council of Plymouth entered into negotiations for obtaining a plot of ground for the site of an infectious disease hospital. Pending the negotiations the epidemic ceased, and now that the Council is called upon to ratify the terms for the purchase of the site and give instructions for obtaining money for the purpose, doubts have arisen among the members as to the advisability of erecting a hospital at all, and it is obvious from recent proceedings that those members who are favourable to the scheme have cooled in their desire for its completion. Indeed, epidemics are fleeting; and it is clearly the opinion of several members of the Council that when over they are best forgotten. But, unfortunately for this easy-going view of the question, the Council are not allowed to forget, by reason of the Local Government Board continually refreshing their memory. Indeed the Council have to meet two evils—the evil of epidemics, which, however, recur only at intervals; and the evil of the Local Government Board, which they find to be a persisting one. The former evil may be conveniently forgotten at times, but the latter not; and the Council would appear to have promised the Central Board to make hospital provision. But, argues one member, the Council will be re-elected in November, and we cannot bind our successors; let us postpone the question in the hope that the next Council may take a different course to the present. Then, argue others, the site proposed to be bought is much too large for a hospital, and it is suggested that a part of it shall be laid out as a recreation-ground; let us convert it all into a recreation-ground. Recreation is a more pleasant way of spending time than rooting out infectious disease from our midst and housing it in a corner. What does it matter that the land has to be bought for hospital purposes? Are municipalities to be governed (Mr. Town Clerk notwithstanding) by rules of morality similar to those which apply to individual rate-payers? This sort of argument very nearly prevailed, for the Council decided to purchase the site, by a majority of one only. The erection of the hospital will still have to be considered, and November is approaching!

THE CULTIVATION OF THE INFECTIOUS DISEASES OF INFANTS.

At a recent meeting of the Orrell Local Board, near Wigan, in Lancashire, the Clerk, in illustration of the difficulties which beset the control of infection, mentioned a practice which exists in that district, of mothers deliberately exposing their young children to the infection of scarlet fever and whooping-cough, under the belief that it was better that the children should have the disease while young. He designated the belief as a "superstition." We would

rather term it a tradition, arising from the imperfectly understood results of experience. The practice described is by no means confined to the part of Lancashire under consideration. Our own knowledge of it is somewhat extensive, but the exposure, so far as we have met with it, has been invariably limited to the obviously mild cases of infectious disease, and two elements entered into the practice. First, there was the practically universal belief that the infectious diseases of children had to be undergone by every child, and the sooner they were got over the better for the child, both as to its chance of recovery and its subsequent welfare; and next there was the belief that if a child contracted the disease from a *mild* case, it would have a mild attack, hence mild cases were selected to *catch* the disease from. In both these elements there was a substratum of truth, which long experience and common observation had shown, and which was unchecked by the more precise observation of the medical man.

DRY ASH AND EARTH CLOSETS IN RURAL DISTRICTS.

Mr. Leonard Armstrong, the medical officer of health for the Newton Abbot Rural Sanitary District, has published in a separate form, for facility of circulation, a pamphlet on the "Advantages and Arrangement of Dry Ash and Earth Closets in Country Districts." The contents of the pamphlet form an appendix to his annual report, and he has done well thus to issue it separately. In this pamphlet he endeavours to show the sanitary advantages which would arise from the substitution of dry ash and earth closets for the kind of privy accommodation which commonly exists in rural districts, and which, as is too well known, usually constitutes the most formidable nuisance in a district. He adds, also, some observations on the disposal of slop-water, so as to avoid nuisance therefrom.

We cannot commend too highly efforts of this kind to instruct sanitary authorities and householders in the essential requirements of health in regard to the common structural arrangements of houses. Mr. Armstrong, moreover, is not content to confine himself to the enunciation of general principles. Convinced that water-carriage of excremental matters is rarely applicable to rural districts, he goes further, and gives plans and instructions for the construction and arrangement of a common privy suitable for them. Privies constructed on this plan would be a great improvement, and we are unwilling to criticise what would be a distinct advance on the common form of privy. But Mr. Armstrong has apparently omitted to observe that the Local Government Board has, in its model bye-laws relating to new buildings, laid down certain principles of privy construction, some of which are not observed in his plan. In a matter of this kind local authorities may not care to come into collision with the Board upon a principle of construction, and it is certainly, in the interest of the subject, desirable to avoid such collision. We should have been glad if the difference in principle could have been avoided in this case, lest it should breed trouble hereafter, and tend to weaken (so ready are people to seek excuses for not doing sanitarily what they ought to do) the beneficial effect which may be looked for from Mr. Armstrong's pamphlet.

SCARLET FEVER AT WARRINGTON—A NOTABLE EXPERIMENT.

Scarlet fever has appeared at Warrington, and the progress of the disease there will be watched with exceptional interest. In 1878 (if we mistake not the date) Warrington obtained from Parliament, in an Improvement Act, which the Corporation then promoted, powers to require the notification of infectious diseases, and, if the local authority deemed fit, for compelling the removal of persons suffering from them to hospital. Previously the Corporation had erected a hospital for the reception and isolation of patients suffering from infectious maladies. The present appearance of scarlet fever in the town is the first which has occurred, we understand, since the hospital was completed and the Corporation were given the extraordinary powers dealing with infectious diseases which are contained in the Improvement Act. Now the Corporation, it seems, aided by their medical officer of health, Mr. Joseph, and after conference with the medical men in the town, are determined to put the powers they possess for the isolation of cases of infectious disease into force, and endeavour to suppress this outbreak of scarlet fever at the outset. The result of this attempt

will be watched with no little interest. Already twenty of the earliest cases of the disease have been isolated in the Corporation hospital; but the disease is reported to be so very mild that it is feared the praiseworthy efforts of the local authority may be largely foiled by the non-recognition of slight cases. The disease, however, is at present confined to one locality of the town; and a house-to-house visitation is now being made there in search of cases; steps, moreover, have been taken to close the schools.

THE MEDICAL OFFICERS' SUPERANNUATION ACT.

A Parliamentary return has been issued showing the number of applications made under the Medical Officers' Superannuation Act (England) to boards of guardians for superannuation allowances. From this return it would appear that since the passing of the Act in 1870, out of 649 unions in England and Wales, applications for allowances have been received from medical officers by the guardians of 108 unions. In these unions 122 applications were made, 70 were granted, 50 were refused, and two had not been decided upon at the date of the return. Among the reasons for refusals of application, we find the following, "the guardians were of opinion that the officer after seventeen years' service, had been sufficiently paid for what work he had done;" in two instances, after forty-one and forty-two years' service respectively, "the officer was comfortably off;" in one instance, after forty-two years' service, the guardians had an "objection to the entire system of superannuation;" in another instance, after twenty-two years' service, because the officer "was not incapacitated by age or infirmity;" he left the union for his own advantage." In several instances superannuation allowances were not granted because the guardians held that the officer had sufficient means from other sources, either as private means or as derived from private practice.

A WHIP FOR SANITARY AND POOR-LAW AUTHORITIES.

It is announced that at a coming diocesan Conference in the West-Midland district the following resolution will be proposed—namely, "That it is the duty of members of the conference to see that the sanitary and other Acts passed for the benefit of the poor in their parishes are more carefully carried out than at present is the case in many districts." If this resolution be adopted the sanitary and poor-law authorities of the particular diocese must look for a troublesome time; but they may console themselves with the thought that if the supporters of the resolution have no clearer notion of the purposes of the sanitary "and other Acts" referred to than would appear from the phraseology above quoted, their active interference is likely to prove more harmful to their own influence than beneficial to their poor parishioners. If clergymen were to set themselves intelligently to cultivate among ratepayers a closer attention to, and more active supervision of, the doings of their sanitary and poor-law representatives, they would contribute to a great and much-needed work, and more certainly secure the objects which it may be presumed are had in view in the resolution quoted.

THE CONTROL OF INFECTIOUS DISEASES.

The growing interest of the profession, as we are pleased to think, in the question of the control of infectious diseases, is indicated in a pamphlet from the pen of Mr. Donald Murdoch, M.R.C.S., on the necessity for further suppression of infectious disorders, just published by Stanford. Mr. Murdoch, in common with many other medical men, sees that the present provisions of the law for preventing the spread of infection are very inadequate, and he offers various suggestions by which he thinks the law might be amended, and medical men and sanitary authorities enabled more effectually to hold in check infectious disorders. He views the matter chiefly from the medical point of view, and with reference to the help which might be given by medical men in bringing about the end he aims at; and he has not quite adequately appreciated in his recommendations the difficulties which influence legal men, magistrates, and sanitary authorities in dealing with the subject. He attaches primary importance to the recommendation that every legally qualified medical practitioner shall give notice to the sanitary authority of every case of infectious disorder that occurs in his practice, within twelve hours (twenty-four in rural districts) after the recognition of the complaint by him, and here at least he will find himself in accord with a large proportion of public-health reformers.

THE DRAINAGE OF WORKHOUSES.

The Local Government Board has issued a circular to Boards of Guardians relative to the drainage of workhouses. Nothing could well be better than the advice given in it, and altogether it forms an excellent summary of the primary requirements of the drainage of buildings. But the puzzle of the matter is this, that advice of this sort should at this late date be required in institutions so long and so rigidly (as it is presumed) supervised. So it is, however, and the circular states that the Local Government Board have had under their consideration the reports made from time to time by their inspectors regarding the system of drainage in operation at various workhouses and other poor-law institutions, and it is evident to them that in many instances the arrangements in this respect are not as satisfactory as could be desired. If guardians go wrong now as to drainage arrangements, in view of this circular, it must be from pure parochial perversity, and we may be permitted to hope that, in future, workhouses, and particularly the new ones, will furnish examples of such drainage as domestic dwellings should possess.

Dr. Griffin, medical officer of Louisburgh Dispensary district of the Westport Union, in a late report to the Local Government Board, states that a permanent fever hospital at Louisburgh is absolutely indispensable. The attention of the Westport guardians has been recently directed to this matter by the Board, but the former appear to doubt the necessity, and have requested Dr. Griffin to produce the names of the thirty-one fever patients stated to have been under his care.

A broker in the Borough has been heavily fined for having, under a distress warrant, removed articles of furniture and bedding from a room in which a patient suffering from small-pox was lying, and offered them for sale without previous disinfection.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

The high rate of urban mortality last week was again caused by the fatality of summer diarrhoea. In twenty of the largest English towns, estimated to contain in the middle of this year seven and a half millions of persons, or nearly one-third of the entire population of England and Wales, 5191 births and 3490 deaths were registered last week. The births exceeded by 6, and the deaths by 215, the average weekly numbers during 1879. The deaths showed, however, a decline of 77 from those returned in the previous week. The annual death-rate per 1000, which had risen steadily from 18.9 to 24.8 in the seven preceding weeks, fell last week to 24.3. During the past seven weeks of the current quarter the death-rate in these twenty towns has averaged 22.3 per 1000, against 25.5 and 17.8 in the corresponding periods of 1878 and 1879. The lowest death-rates in the twenty towns last week were 16.0 in Brighton, 16.4 in Bristol, 19.9 in Wolverhampton, and 21.3 in London. The rates in the other towns ranged upwards to 31.5 in Manchester, 33.1 in Salford, 34.5 in Leicester, 34.8 in Plymouth, and 39.7 in the borough of Hull. The high death-rates in these last-mentioned towns were mainly due to excessive diarrhoea fatality.

The deaths referred to the seven principal zymotic diseases in the twenty towns, which had steadily increased from 406 to 1100 in the ten preceding weeks, further rose to 1136 last week. These included 864 from diarrhoea, 105 from scarlet fever, 60 from whooping-cough, 48 from measles, and 40 from different forms of fever. The annual death-rate from these seven diseases averaged 7.9 per 1000 in the twenty towns; and while it was but 2.9 and 3.9 in Bristol and Brighton, it ranged upwards to 15.0 and 24.1 in Hull and Leicester. Scarlet fever showed the largest proportional fatality in Oldham and Leicester. Three deaths from diphtheria were returned in Birmingham. Small-pox caused 4 more deaths in London, but not one in any of the nineteen large provincial towns. The number of small-pox patients in the Metropolitan Asylum Hospitals, which had steadily declined in the four preceding weeks from 200 to 134, were 135 on Saturday last; 30 new cases of small-pox were, however, admitted to these hospitals during the week, against 15 and 20 in the two previous weeks. The Highgate Small-pox Hospital contained seven patients on Saturday last.

The fatal cases of diarrhoea in the twenty towns, which

in the nine preceding weeks had steadily increased from 51 to 807, further rose last week to 864. The annual death-rate from diarrhoea averaged 6.0 per 1000 in the twenty towns; it was equal to 3.8 in London, and to 8.1 in the nineteen large provincial towns. The death-rate from diarrhoea among the twenty towns ranged last week from 1.7 in Bristol, to 12.9 in Hull, and 20.1 in Leicester. In the last-mentioned town the diarrhoea rate has risen from 3.6 to 20.1 during the past four weeks.

The deaths referred to diseases of the respiratory organs in London, which had been 175 and 152 in the two preceding weeks, were 167 last week, and exceeded the corrected weekly average by 26. Of these 167 deaths 93 were attributed to bronchitis, and 48 to pneumonia. The annual death-rate from diseases of this class was equal to 2.4 per 1000 in London, and 3.7 in Liverpool.

HEALTH OF SCOTCH TOWNS.

In eight of the largest Scotch towns, having an estimated population of rather more than a million and a quarter persons, the annual death-rate last week averaged 18.6 per 1000, and was below the mean of the six preceding weeks; this rate was 5.7 below the average rate in the twenty large English towns. The rates in the eight Scotch towns ranged from 9.7 and 14.6 in Perth and Aberdeen, to 20.4 and 27.6 in Leith and Paisley. The deaths from the seven principal zymotic diseases in the eight towns were 127, against 125 and 122 in the two preceding weeks; they included 65 from diarrhoea, 22 from whooping-cough, 17 from scarlet fever, 8 from measles, 8 from diphtheria, 7 from fever, and not one from small-pox. The annual death-rate from these seven diseases averaged 5.1 per 1000 in the eight towns, against 7.9 in the large English towns. The excess of the zymotic death-rate in the English towns was almost entirely due to the greater fatality of infantile diarrhoea. There were no deaths from the seven zymotic diseases in Perth, and the zymotic rate was but 1.5 in Aberdeen, whereas it ranged upwards to 8.0 and 8.5 in Leith and Paisley; the excess in the zymotic death-rate in Leith was due to scarlet fever, and in Paisley to diarrhoea and whooping-cough. The fatal cases of diarrhoea in the eight towns, which had declined in the week before last to 51, rose again last week to 65, a higher number than has been returned in any week of the current quarter. The annual death-rate from this disease did not average more than 2.6 per 1000, while in the English towns the rate was equal to 6.0. The highest proportion of fatality of diarrhoea in the Scotch towns occurred in Greenock and Paisley. The 22 deaths from whooping-cough included 9 in Glasgow, and 7 in Edinburgh. Seven of the fatal cases of scarlet fever occurred in Glasgow and 6 in Leith. Four of the deaths from measles were returned in Glasgow; and diphtheria caused 3 deaths in Edinburgh, 2 in Glasgow, and 2 in Dundee. The deaths referred to fever, which had been 13 and 17 in the two previous weeks, declined last week to 7, of which 6 were recorded in Glasgow. The deaths attributed to acute diseases of the lungs (bronchitis, pleurisy, and pneumonia) were 39 in the eight Scotch towns last week, against 67 and 70 in the two preceding weeks; the annual death-rate from these diseases was equal to 1.6 per 1000, against 2.4 in London. The causes of 81, or 17 per cent., of the 463 deaths registered in the Scotch towns last week were uncertified; in the English towns the proportion of uncertified causes of death was scarcely two per cent.

HEALTH OF DUBLIN.

The rate of mortality again showed a marked excess in Dublin last week, and was equal to 37.8 per 1000, against 35.3 in each of the two preceding weeks. During the past seven weeks of the present quarter the death-rate in the city has averaged 32.6 per 1000, against 22.1 in London, and 17.9 in Edinburgh. The 228 deaths in Dublin included 56, or no less than 25 per cent., which were referred to the seven principal zymotic diseases, showing but a slight decline from the high number returned in the preceding week; 5 resulted from small-pox, 3 from measles, 15 from scarlet fever, 3 from whooping-cough, 5 from different forms of fever, and no less than 25 from diarrhoea. The annual death-rate from these seven diseases was equal to 9.3 per 1000 in Dublin last week, against 5.6 in London, and 4.8 in Edinburgh. The fatal cases of small-pox and measles showed a decline from recent weekly numbers. The deaths from scarlet fever corresponded with the number returned in the previous week. The fatal cases of diarrhoea, which had

averaged but 4 weekly during July, rose successively to 9, 23, and 25 in the first three weeks of August, and were equal to an annual rate of 4·1 per 1000; this rate, however, was considerably below the average rate in the twenty large English towns.

INFANTILE DIARRHOEA IN LEICESTER.

Infantile mortality has begun during the past few weeks to show the marked increase in Leicester which usually takes place in that time during the season of summer diarrhoea prevalence. The weekly number of deaths registered under one year of age in that town, which averaged but 13 during June, steadily and rapidly increased during July, and were successively 30, 42, and 48 in the first three weeks of August. This increase is almost entirely due to diarrhoea fatality, which caused but 2 deaths in June, 25 in July, and 19, 26, and 50 respectively in the three weeks ending last Saturday. The excessive fatality of diarrhoea in Leicester has been the subject of much investigation and many theories, but it cannot be separated from the fact that the rate of infant mortality from all causes is excessive in Leicester, and that the excess in the rate is only partially accounted for by the fatality from diarrhoea. During last year the proportion of deaths under one year to births in Leicester was 185 per 1000, although the year was remarkable for the small recorded fatality of diarrhoea. The nearest approach to so high a rate of infant mortality in the twenty large towns dealt with in the Registrar-General's weekly return occurred in Salford, where, however, the rate did not exceed 170 per 1000. Dr. William Johnson, the Medical Officer of Health for the borough, freely admits in his last report—what he was previously inclined to dispute—that the excessive death-rate of infants in Leicester is not confined to diarrhoea. During the ten years 1870–79 infant mortality in those twenty towns averaged 171 per 1000, and ranged from 141 and 158 in Portsmouth and London, to 216 both in Leicester and Liverpool; the nearest approach in the other towns was 192 in Leeds. Dr. Johnson in his last report gives some valuable and interesting tables conclusively proving what we have frequently noticed in these columns in connexion with the high rate of infant mortality in Leicester—namely, that the death-rate in the borough at all ages above one year not only compares favourably with the rates in other large towns, but is below the standard English life table rates at those ages. His suggestion that crèches or nursing-homes should be established under medical inspection, and visited by Ladies' Committees, is a useful one, but something more must be done before Leicester will lose the stigma which now attaches to it as the town in which infant life is least successfully cared for among our largest towns. Dr. Johnson wisely exposes the fallacy of attributing the high rate of infant mortality to the high birth-rate; we cannot, however, agree with him in regarding the high birth-rate in Leicester as a natural consequence of the excessive infant mortality. For the cause of the high birth-rate in Leicester it is unnecessary to look much beyond the fact that the town population includes an abnormally large proportion of young adults.

HEALTH MATTERS GENERALLY AT HOME AND ABROAD.

THE SANITARY COMMISSIONERSHIP OF INDIA.

A correspondent of the *Pioneer*, evidently well informed, questions the wisdom of doing away, at the present time, with the post of Sanitary Commissioner with the Government of India. Dr. Cunningham's reports, it is observed, have done this signal service, that they have shown clearly that very nearly half of the total deaths of the troops are due to three of the most easily preventable of all diseases—namely, cholera, typhoid fever, and dysentery. Of the total of 1212 deaths in the European army in India in 1878, cholera caused 226, typhoid 258, and dysentery 98, or altogether 582 out of 1212. Thus by abolishing the causes of these three diseases, the death-rate of the troops would be reduced nearly one-half. Dr. Cunningham has not had time apparently to make an exhaustive inquiry into the causation of disease at different stations. His reports are limited to mere expositions of numerical results without reference to the causes. But the time has now come for taking up systematically the investigation of the causes of

sickness in each station on the plan which has been pursued for many years with remarkable success in England by the medical inspectors of the Local Government Board. One single example will show how important it is that such an investigation should be made. In olden days Jullundur was one of the healthiest stations in India, and for the last year it has been one of the most unhealthy, and this change in its condition has coincided with the erection of barracks on which a vast outlay was incurred. These barracks were first occupied in 1872, and between that year and 1878 the occupants of them have suffered from three severe epidemics—viz., in 1872 cholera and typhoid, 1875 typhoid, 1878 dysentery and typhoid. It is very singular, too, that while the occupants of the new barracks have been unhealthy, the artillery, who continue to occupy the old style of barracks, remain in the enjoyment of the good health of former times. The death-rate per 1000 of the two bodies is shown in juxtaposition as follows:—

	1872.	1875.	1878.
European Infantry, new barracks...	31·8	18·75	66·28
Artillery, old barracks ...	14·29	6·25	5·99

"I feel satisfied," says the writer, "that if this remarkable case were studied with the same exhaustive thoroughness as has been brought to bear for some years on the study of epidemic outbreaks in England, a flood of light would be thrown on the causes of disease, not in this particular instance only, but in all other stations where dysentery, cholera, and typhoid fever prevail. But the very moment when problems of this kind were pressing on for solution, has been chosen for abolishing the appointment of Sanitary Commissioner altogether."

THE INTERNATIONAL RED-CROSS HOSPITAL, BADEN.

The Russian journal, the *Béreg*, states that after the Franco-German war the central committee of the Russian Red Cross Society established a hospital at Baden for sick and wounded soldiers. These were provided with medical and surgical treatment and food at the expense of the society, and 338 patients were received into the hospital, of whom 183 were discharged cured, 183 improved, and 16 without having received benefit from their residence there. After the Russo-Turkish war the Red Cross Society re-established a hospital at Baden, but to the time of the *Béreg* giving this notice, only one Russian soldier had been sent there. Dr. Heidenreich, the principal medical officer, believes that this must have arisen from the existence of the hospital not having been made sufficiently known by those likely to profit by it, and he appears to have asked the intervention of the Russian press in publishing information concerning the hospital.

SCAVENGING IN DUBLIN.

The Dublin Corporation had last Monday under consideration a report of the Committee appointed in February last to deal with the question of public and domestic scavenging. The Committee, after receiving the report of a deputation which visited Glasgow, Manchester, Liverpool, and other towns in December last, and obtaining from the City Engineer and the executive officer of the Public Health Committee reports embodying their opinions as to the best means to be adopted, have recommended that the Corporation should take entire charge of the scavenging, and have the same carried out by their own staff under a competent manager. The expense of the department is estimated at £28,700 per annum, or a trifle over one shilling in the pound on the city rates. The report has been adjourned for a future meeting of the Council.

THE RUSSIAN RED-CROSS SOCIETY.

A *Te Deum* was announced to be celebrated in St. Petersburg on the 14th instant on the despatch of certain sisters of charity of the Community of the Exaltation of the Holy Cross to the assistance of the sick and wounded of the expedition to Akhal-Teké. Countess Elizabeth Milintine, one of the sisters, accompanies the detachment, and Dr. Stcherbak is attached to it as delegate of the Red-Cross Society. The assistance despatched by the Red-Cross Society to the expedition, in nurses, medical men and material, did not reach the scene of action until the operations of the troops had terminated. The efforts of the Society were therefore directed to the amelioration of the state of the sick and wounded they found in hospital on both coasts of the

Caspian, but particularly on the Caucasian coast, where the greater number had been removed by the military authorities, and distributed in the hospitals of Baku, Temir-Khan-Schoura, Petrovsk, Grozny, &c.

REPORTED CHOLERA IN RUSSIA.

Russian journals report an outbreak of "cholera" at Saratov, on the Volga. The scanty particulars given suggest that the report refers to an outbreak of choleraic disease, probably caused by the consumption of some poisonous article of food, after the manner of the recent fatal choleraic outbreak at Welbeck.

WOOD PAVEMENT.

The Commissioners of Public Works have sanctioned a loan of £4000, part of the loan of £100,000 for the paving of Dublin, to be expended on wood pavements in certain portions of that city.

A further extension of diphtheria in the Government of Poltava, Southern Russia, is reported.

New Inventions.

DAY'S SPLINT FOR HIP-DISEASE.

THIS splint, which is the invention of Mr. E. O. Day, the medical officer of the Royal Hospital for Children and Women, is a modification, and we think an improvement, on Thomas's splint. It consists of a foundation rod, A A, extending behind the affected limb and the trunk. At its upper end this rod is recurved, so that any tendency to flexion when the child is raised by the foot is obviated. At its lower end there is a movable foot-piece which allows for growth, a very important matter to bear in mind when dealing with the chronic maladies of childhood. The trunk is grasped by two stirrup-shaped metal bands, which can be accurately fitted to the size of the body by means of slots and screw clamps. In this again we have a provision for growth and a possibility of utilising the same splint for more than one case. These bands being flat behind, prevent any

rolling movement of the apparatus, or any tendency of the foundation-rod to get to the outside of the limb. The thigh of the affected limb is surrounded by a circular metal band, also fastened by a slot and clamp. These three bands are united along their anterior aspect by clamps to a rod, B B, and thus the affected joint is enclosed in an absolutely rigid cage, while additional security is afforded by a flat brass rod, C, which is accurately fitted to the curve of the groin, and thus the perfect fixity of the joint is secured.

It is claimed for this splint that it is less cumbersome than most others, that it thoroughly immobilises the limb, maintains the parallelism of the legs, and dispenses with bandaging, and it certainly appears to us to be capable of doing all that is claimed for it. It is made by Mr. Eastgate, 73, Neale-street, Long-acre.

THE SERVICES.

WAR OFFICE.—1st Life Guards: Surgeon Henry Frank Hensman, from the 2nd Life Guards, to be Surgeon-Major, vice O. W. George, M.D., granted retired pay, and to have the honorary rank of Brigade-Surgeon; dated June 29th, 1880.

ARMY MEDICAL DEPARTMENT.—Brigade-Surgeon Thos. Teevan has been granted retired pay, with the honorary rank of Deputy Surgeon-General; dated July 30th, 1880. The promotion to the rank of Brigade-Surgeon of Surgeon-Major Charles Carroll Dempster is antedated to November 27th, 1879, such antedate not to carry pay prior to March 27th, 1880. Surgeon-Major Leslie Ogilvy Patterson and Surgeon-Major William Creagh are granted retired pay, with the honorary rank of Brigade-Surgeon; dated August 25th, 1880.

Surgeon-Majors to be Brigade-Surgeons:—John George Faught, vice J. P. Cunningham, M.D., promoted; dated April 17th, 1880. William Henry Muschamp, vice J. O'Nial, promoted; dated May 26th, 1880. Edwin James Hopwood, vice T. S. Hollingsworth, granted retired pay; dated June 9th, 1880. Stewart Aaron Lithgow, M.D., vice J. Hannan, deceased; dated June 13th, 1880. William George Nicholas Manley, V.C., vice T. W. Fox, M.B., promoted; dated June 23rd, 1880. Oliver Barnett, vice W. Macnamara, M.D., granted retired pay; dated July 21st, 1880.

G. R. Gilruth, gent., to be Acting Surgeon to the 1st Edinburgh Corps of Volunteer Artillery; dated Aug. 21st, 1880.

ADMIRALTY.—Fleet-Surgeon George Mason, M.D., has been promoted to the rank of Deputy-Inspector-General of Hospitals and Fleets, with seniority of the 20th instant. The following appointments have been made:—Fleet-Surgeon W. Ross, M.D., to the *Duncan*, additional for temporary service; Staff-Surgeons W. H. Stewart to the *Cleopatra* (when commissioned); Robert Turner to the *Duke of Wellington*, for the *Victory*; Thomas S. Burnett to the *Valiant*; Jephson J. Connell to the *Cleopatra*; M. F. Ryan to the *Valiant*; A. Turnbull to the *Bacchante*; G. Maclean to the *Duke of Wellington*, additional for Haslar Hospital (for temporary service); G. M. Cuffe to Haslar Hospital.

Surgeon-General G. A. F. Shelton, Army Medical Department, has been appointed to succeed Surgeon-General William Munro, C.B., as Head of the Medical Branch, War Office, Whitehall Yard.

Deputy-Surgeon-General Stanhope H. Fasson, M.D., has been ordered to Aldershot, as Principal Medical Officer, vice Surgeon-General Shelton.

Brigade-Surgeon J. Ogilvy, M.D., has been transferred from Portsmouth to Aldershot on promotion, and will act as Sanitary Medical Officer of that garrison.

FRENCH NAVAL MEDICAL SERVICE.

It would appear that the British is not the only Navy which experiences a difficulty in recruiting medical officers. The French, notwithstanding the existence of three schools of medicine for the Navy supported by the Government, find the supply of candidates unequal to the requirements of the Service. To remedy this, a reorganisation of the Medical Department has been proposed in connexion with the scheme submitted respecting the *cadres* of the Navy. As the subject of attracting to the Service a sufficient number of well-qualified officers is believed to be at present under the consideration of the Admiralty in this country, it may not be without interest to our readers to see what is proposed to be done in France. The Department is to consist of two branches—the Medical and the Pharmaceutical; and these, again, are subdivided into the Health Service (*service de santé*) and the Educational Service (*service d'enseignement*). The following is the proposed scale of officers:—

Medical Branch.

- | | | |
|----|---|------------------------------|
| 1 | Inspector-general of the health service, ranking with rear-admiral. | |
| 3 | Directors of instruction, | } ranking after rear-admiral |
| 2 | health service, | |
| 1 | Medical inspector. | } and before post-captain. |
| 10 | Chief medical officers of instruction, | } ranking with |
| 12 | general service, | |

- 13 Medical professors, } ranking with commanders.
 40 Principal medical officers, }
 200 Medical officers, 1st class, ranking with lieutenants.
 250 " " 2nd class, ranking with sub-lieutenants.
 150 Assistant medical officers, ranking with midshipmen.

Pharmaceutical Branch.

- 1 Apothecary-inspector.
 5 Chief apothecaries of instruction.
 1 Chief apothecary, general service.
 6 Professors.
 3 Principal apothecaries.
 20 Apothecaries, 1st class.
 28 " 2nd class.
 28 Assistant apothecaries.

The apothecaries are to have the same relative rank as the corresponding grades of the medical branch. The professors are to be appointed by competitive examination from the principal medical officers and apothecaries, or those of the first class; and the higher grades of the educational branch are to be filled by selection from the professors. The staff of each of the naval medical schools consists of six medical and three pharmaceutical professors, with five assistants. It is proposed to add two professors to each school.

The relative rank to be granted to the medical officers is, we believe, a new feature in the French Navy, and will tend more than anything else to raise the prestige of the department and remove the difficulty which has been found in obtaining candidates for it. We trust that in our own service the Lords of the Admiralty will remember that an assured position in the service, placed by regulation beyond the petty and annoying interference of individual officers, will do more to render the medical department of the navy popular and ensure a supply of candidates than any mere addition to the pay without the removal of existing grievances.

SERVICE EXAMINATIONS.

The following are the questions in Anatomy, Physiology, Medicine, and Surgery, set at the recent examination of candidates for H.M. Naval, British, and Foreign Medical Services:—

Anatomy and Physiology.

1. Give a description of the ulna; enumerate the ligaments and muscles connected with it, and indicate the points of origin from, or attachment to, that bone.
2. Describe the anatomical relations of the parts that enter into the formation of the inguinal canal, and of an oblique inguinal hernia.
3. Describe the formation of the cervical plexus and its anatomical relations; enumerate the principal branches of distribution, and especially describe the origin, course, and distribution of the phrenics, and the part they take in the mechanism of respiration.
4. Describe the anatomical relations, the structure and functions, of the great intestine.
5. Give a description of the anatomical relations and distribution of the deep femoral artery and of its branches.
6. Describe the glandular structures by which saliva is formed. Give an account of the composition and physiological uses of that fluid.

Surgery.

1. In a case of compound fracture of skull, with depression and symptoms of compression, what treatment should be pursued? Firstly, as regards the fractured bone; and, secondly, the condition of the patient? State what would be the prognosis in such a case, and the reasons for the conclusion arrived at. Describe the process by which any deficiency of bone is made good when recovery takes place.
2. Describe the symptoms of gonorrhoeal ophthalmia, its effects when not arrested, and the treatment to be pursued in its different stages.
3. What are the various causes of gangrene? Describe the symptoms by which each cause may be diagnosed, and the treatment of each variety.
4. Describe the various symptoms of hereditary syphilis, as they occur at different periods of life, and the treatment to be adopted for its relief.
5. Describe the constitutional and local causes which give rise to inflammation of veins, the various consequences liable to occur in such an attack, and the treatment to be pursued.
6. State the symptoms by which a psoas abscess, presenting in the thigh, may be diagnosed from a large cyst in the upper part of the femoral region. What are the pathological conditions attendant on psoas abscess, and what should be the treatment?

Medicine.

1. Describe (a) the causation, exclusive of traumatic causes; (b) the morbid anatomy; (c) the clinical phenomena and possible sequelæ; (d) the treatment of cases of cerebral hæmorrhage.
2. Give an account of (1) the intestinal lesions which are constant in cases of enteric fever, their progress and results in relation to the clinical phenomena; (2) the condition of the minute elements of (a) the glandular organs, (b) the heart, and (c) the voluntary muscles. Give a short summary of (a) the phenomena which are distinctive of enteric fever, and (b) the phenomena which it has in common with other febrile diseases.
3. Describe the symptoms, period of incubation, and usual course of a typical case of scarlet fever, with all its possible sequelæ.
4. Mention the causes, describe the symptoms and the appropriate treatment, of peritonitis.

5. Describe a case of puerperal fever.
 6. Give an account of (1) the source, the physiological properties, and medicinal uses of (a) ergot, (b) belladonna. (2) Name the pharmacopœial preparations and the doses of each of the preparations you name. What are the antidotes in cases of poisoning from them?
- Three hours were allowed for answering each paper.
 Sixty-nine candidates have passed the examination, and will proceed to Netley.

MEDICAL TRIALS.

ARUNDEL COUNTY COURT.

MIDWIFERY CONTRACTS.—VINES V. STUART.

THE judge (Mr. A. Martineau) on August 17th gave judgment in this case, which had been adjourned. Mr. Vines, surgeon, of Littlehampton, had brought an action against defendant for £1 ls. damages for breach of contract in not employing him to attend defendant's wife in her confinement. The plaintiff's case was that, being the medical attendant of the family, the defendant's wife had asked him to attend her in her accouchement, the probable date of which was notified by him. A short time before the event, however, some misunderstanding arose between him and the defendant, and thereupon the defendant gave plaintiff notice that his services in attending the defendant's wife in her approaching confinement would not be required. The judge said (we quote from the *Sussex Daily News*):—"The plaintiff now insists—1st, that there was a definite binding contract on the part of the defendant to employ him, the plaintiff, as a surgeon at the confinement; 2nd, that the damages to which a surgeon is entitled in such a case are liquidated by well-established custom, which fixes them at the fee which the surgeon would have earned; 3rd, that if not liquidated by custom, the proper measure of damage is the fee that would have been earned. I reserved judgment, first to consider the question whether the engagement amounted to a contract, for breach of which an action will lie; 2nd, to consider what the proper measure of damage is. I may observe that my predecessor, in a similar case, decided that the doctor cannot recover damages, but the present Registrar of the County Court at Brighton, who argued the case of the doctor before Mr. Furner, having informed me that he had seen an article in a medical journal commenting on that decision, and referring to a case in the High Court, in which a judge had laid down that the measure of damage is the fee that would have been earned, I reserved judgment, hoping to find the case, but I have not been able to do so. I have, however, found a decision of the High Court reported, which tends to show that the measure of damage is different. I must, however, first dispose of the question whether the damages are liquidated by custom at the amount of the fee that would have been earned; and I feel no difficulty in holding that no such custom is proved. It would, I think, be very unreasonable that the damages should be the fee that would have been earned, for the surgeon would then get the same sum without responsibility or labour that he would have earned with responsibility and labour; and to establish such a custom, I should require the evidence, not only of medical men, but of patients, showing that the custom is well known to and accepted by those who employ as well as those who are employed. I hold, therefore, that in this case the damages are not liquidated, and assuming that there was a binding contract the damages must be ascertained by me, sitting as a jury, and they must be measured in the ordinary way, and upon the principles applicable in cases of breach of contract. The proper way to arrive at the damages (if any) is to take into account on the one hand that if the alleged contract had not been broken, the surgeon would, in all probability, have earned £1 ls., but inasmuch as he would have earned that sum only with a certain amount of responsibility, loss of time, trouble, and labour, from which he has been freed, a corresponding deduction should be made from the £1 ls., the fee that would have been earned; and if I were to deduct 10s. 6d., leaving the surgeon with half a fee, my impression is that I should be very liberal to the surgeon, and that if he had had his choice between £1 ls. as remuneration for a great deal of trouble, and 10s. 6d. for doing nothing, he would have preferred the half guinea. I see my way, therefore, to the proper amount of damages, if there has been a breach of contract, for which an action will lie. But I have much more difficulty on the question of contract. I have no doubt

that a binding contract to employ a surgeon on some future day may be entered into, and in some cases I have no doubt such a contract is entered into; but I doubt very much whether the loose conversation between a surgeon and a lady in reference to the former attending her in her confinement on some distant day amounts to a definite binding contract, or that it is intended by either party that it should. The plaintiff lays stress on the fact that he made an entry in his books of the date in the presence of the defendant's wife, and that he could not leave home or go to a distance as long as he was under the engagement to attend. I do not think that alters the case. If there was a constraint there was no doubt consideration on both sides. I should observe—though this perhaps goes more to the question of the damages to which the plaintiff would be entitled if there were a contract—that for anything that appears to the contrary, the plaintiff in this case was fully employed and earning fees from other patients throughout the time that he would have had to devote to the defendant's wife if she had sent for him, and that he may have lost nothing. I lay no stress on the fact that the defendant gave notice to the plaintiff that his services would not be required before the event came off, or that the defendant having told the plaintiff that he had no confidence in him and did not want his services as medical attendant any longer. The plaintiff insists that, nevertheless, he ought to have been sent for. That is a mere matter of delicacy, as to which I say nothing, this being a court of law and not a court of delicacy. I think what passed between plaintiff and defendant's wife in this case did not amount to a definite contract upon which an action will lie. There will, therefore, be a verdict for the defendant, with costs."

SHEFFIELD COUNTY COURT.

Before T. Ellison, Esq. (Judge).

MASON v. PECK. — Mr. James Mason, surgeon, sued William Peck, mechanic, for £11 7s. 6d., for surgical assistance. Mr. E. Knowles Binns represented Peck. Defendant is a member of the London and Manchester Industrial Assurance Company, of which the plaintiff is the local medical officer. Peck, whilst ill, was attended by Mr. Mason. The plaintiff sought to recover the debt on the ground that surgical operations were necessary in the case, and his agreement with the Insurance Company did not provide for the payment by it for that kind of work. The defence was that surgical assistance was not at all requisite in the treatment, and that the claim was thereby unsubstantiated. Mr. Knowles Binns said he had not seen the agreements with the society. He wished to do so before the case was decided. His Honour said he never had a more important case before him since he sat in the court, and he thought Mr. Mason should be represented by a solicitor. Mr. Binns, wishing to argue the points, the hearing would have to be adjourned. The case, according to arrangement, will come on on Nov. 12th.

Correspondence.

"Audi alteram partem."

REGINA v. INGLE: THE PENAL TREATMENT OF DISEASE.

To the Editor of THE LANCET.

SIR,—The letter of Dr. Pavy in your last number is a complete vindication of his action in this deplorable case. One point—that on which it was attempted to build a justification for the nurse—deserves, however, further consideration. Dr. Pavy says: "A great deal more was made of hysteria in connexion with the case at the trial than it was entitled to receive. The nurse in the inquiry before the treasurer had excused herself by saying that she had been given to understand that the patient was suffering from hysteria, and that she thought she was only putting in force the proper treatment."

This plea, of course, is rightly repudiated by Dr. Pavy. Still, that it should have been put forward and received to any extent is evidence of the persistence of an error, which

is a reproach to medical science, and fraught with danger. This must be my excuse for offering the following observations.

Assuming this plea to be the real line of defence, three things are implied: 1, that hysteria is a disorder rather moral than physical; 2nd, that, therefore, hysteria may properly be treated on penal principles; 3rd, that a nurse is competent, of her own motion, to apply that treatment. If we admit the first proposition, the second *might*, perhaps, be accepted with some reservation; but admitting both, it would not follow that a nurse, acting on her own discretion, is competent to administer the penal treatment. But is it possible, in the actual state of medical science, to contend that the symptoms to which the conventional term "hysteria" is applied really constitute a morbid entity, or a special perversion of the moral element? In other words, is there such a thing as hysteria independent of bodily disease? I venture to affirm that there is not. Wherever the phenomena known as hysteria present themselves, there is surely underlying them as cause a pathological condition which it is the business of the physician to discover and to treat. To treat hysteria medicinally is to treat a symptom—a course sometimes judicious, but hardly scientific. To treat hysteria penally is, in plain language, to treat the patient brutally. Hysteria is no more an independent disease than is neuralgia, chorea, epilepsy, or other overt manifestation of disease or disorder of the nervous centres. As well might we apply penal treatment to these nervous phenomena as to hysteria. The penal treatment of hysteria is a remnant of the barbarous era of medicine, when lunatics were so treated. A favourite mode of treating lunatics in that barbarous period was by subjecting them to a protracted cold bath; and it is not a little curious to note that this was the remedy administered to the unfortunate woman at Guy's.

It may be freely conceded that in young women said to be hysterical there is a moral factor in the case which requires judicious moral management in addition to the more strictly medical treatment indicated by the underlying pathological conditions. But the physician must be extremely careful lest in the adoption of moral means he overstep the legitimate bounds of his profession, and trespass on the territory of the civil magistrate. And this it will be very difficult to avoid if he fall into the fundamental physiological error of supposing that moral or physical punishment is an essential element in the treatment of hysteria. Taking this view—one which cannot be overlooked—does it not follow that the physician who, without adequate safeguards, makes punishment a part of his *materia medica*, runs imminent risk of coming into collision with the law? Or to apply the argument to the case at Guy's, and supposing that the patient had suffered no injury from the cold bath, still, had not an assault been committed upon her?

Whether it be contended that hysteria is a moral perversion demanding punitive treatment or not, surely it is equally beyond the province of the physician, and, *à fortiori*, of the nurse, to administer it in this fashion. But I cannot help repeating emphatically that to regard hysteria as a moral disorder that can be usefully treated on penal principles is utterly unjustified by the actual state of medical knowledge. If we still use the word hysteria as "giving a name" to a disease, it ought only to be done provisionally, whilst we are searching for the morbid cause. Hysteria in this light, then, is simply an "asylum ignorantiae"; an asylum which it is time to close.

Before concluding these observations on the penal treatment of disease, there is one more remark I am tempted to make. The recent movement for instituting a distinct Faculty of Nursing as something independent of the authority of the Faculty of Medicine is one which concerns the public even more vitally than it does the physician. However much the physician may be pained and harassed at seeing his best efforts thwarted by the perverseness of the nurse, after all it is the patient who suffers most. If those very ignorant, and, therefore, very presumptuous enthusiasts who foster this "new system of nursing" were to make themselves the first subjects of the experiment; well, this new form of vivisection might find justification! But when ignorance and presumption perform dangerous experiments upon the helpless poor, whose inheritance is dependence upon charity, then this vivisection assumes the more odious character of cruelty, if not of something worse.

I am, Sir, yours, &c.,

ROBERT BARNES.

Harley-street, August 24th, 1880.

GUY'S HOSPITAL AND THE OFFICE OF TREASURER.

To the Editor of THE LANCET.

SIR,—The misdoings and mismanagement at Guy's having been now very freely discussed, it might be well, with a view to bring good out of evil, to see how the hospital despotism complained of came to be; how it became centred in the office of Treasurer naturally and necessarily; how the conditions of society and of these institutions are now so changed that the office as administered can no longer be tolerated; and, this done, the remedy would seem to be easy. The earlier hospitals—notably St. Thomas's, of which Guy's is to some extent an acknowledged offshoot and copy—admitted not merely the sick but the foundling and the depraved; the charter of Edward VI. gave powers accordingly for the management. At the weekly meetings of the Court of Governors in those early times are frequent notices of delinquents tried, sentenced to whipping and other punishments. A whipping-post, called “the crosse,” within the precincts, was in constant use, as its renewal and frequent repair shows. Even Sisters were whipped—notably Jane Thornton, in 1570, whose offence was no doubt grave, as the twelve stripes ordered were to be “well laid on;” others, younger, seem to have been privately whipped by the matron. Many with diseases the result of vice were first cured, then whipped or put in the stocks, as a warning before they were dismissed. Diseases pure and simple bearing upon insanity, or those lesser insanities which we call hysteria, were treated with punishment.

It was convenient to delegate many of these matters to the Treasurer and Matron. The power entrusted chiefly to the Treasurer was bit by bit enlarged, so that down nearly, if not quite, to our time this official became a despot. In the Order of the Hospitals, 1557,¹ the Treasurer's charge is acknowledged to be one of much pain and “attendance.” He may supersede the physician and surgeon in many particulars of their special office; certain malefactors are brought before him, and with the aid of one almoner he may examine, commit to prison, reprove, banish, put to labour, or being “diseased” may admit to the hospital. Here we see the *fons et origo* of the Treasurer's office, and can traditionally account for the hankering after the punitive which still remains. The late case would have been but an instance of old legal custom, and the tone of the old power is manifested when the Treasurer excuses the nurse in that it was but an error of judgment, which unhappily ended in death. These errors in judgment must, however, frequently recur in connexion with punitive treatment, or what may amount to nearly the same, treatment without the intelligent and responsible supervision of the doctor. Guy's has been officially noted as the place in which mischief was likely to appear. The Charity Commissioners, in their Thirty-Second Report (part vi., p. 780), say of Guy's: “One most important subject yet remains to be noticed—namely, the absolute and uncontrolled authority which is practically enjoyed by the present Treasurer (1840) in every department of the charity. Not only is the administration of the hospital in the management of the funds entirely in his hands, but the nomination of Governors seems mainly to rest with him. . . . Entire control of the Medical School is with him, in his private and individual capacity. He names the lecturers, exercises a sovereign and irresponsible authority. So large a concession appears to be unjustifiable.” They also say that “much confusion and injury may be anticipated as the result of the system.” This is signed, “Samuel Smith and Francis Offley Martin, Charity Commissioners.”² One of the greatest of Guy's modern teachers, James Blundell, notes as the root of the evil which existed then, as now, that “the hospital schools are governed by men not intended for the office, and seldom adequately prepared for so important a trust.” Although in some few particulars changes may have been made since 1840, the office is in the main managed as ever. The late Treasurer of Guy's acted, as he owned, upon his own personal responsibility, and used the hospital nurses in a case of quasi-medical police—that of the Welsh fasting girl Jacobs;³ and the doings of the present Treasurer, introducing vital changes in the

management of patients, without even the knowledge, much less the approbation, of the medical staff, prove that the office is as irresponsible as ever. I do not so much blame any personal Treasurer as I do the vicious system of giving such peculiar authority to a man destitute of medical knowledge. When the treatment of disease was quackish, astrological, and what not, and when the patients were not unfrequently of the scum of society, it might have been necessary; but now that these institutions are worked by men of the highest qualifications, by men fitted to grace the highest intellectual circles, and now that the practice of medicine and surgery has become a science, it is a barbarism to continue in the same way.

And now to the remedy. In the action at law *re* St. Thomas's Hospital, 1862, the Chancellor who tried the case acknowledged, as did the Attorney-General, that the parishes had an interest in the honest and judicious management of the great charitable institutions established in their midst exclusively for the sick and suffering poor, and that they therefore had a *locus standi*. Now, these doings at Guy's call for prompt and energetic action; the parishes may well take action once more. I do not think for a moment that the Charity Commissioners are equal to this work. It must, I think, be done by a Committee of the House of Commons; as the case lies in a nutshell, two or three days might suffice for a report. The evil and the results are of a magnitude enough to justify this course. It is for the South London parishes by their boards and vestries to petition for inquiry; action in this way in at least one parish is already promised, and the members for the borough would be glad to help. Even if the House has no time for this now, the demonstration would be of service against next session. The remedy would seem to be the abolition of the office of Treasurer, or of any government, directly or indirectly, by any one man, and to appoint a real, working, openly responsible committee of management, on which committee the medical staff must be adequately and efficiently represented. Perhaps the local governing bodies might once in three years appoint, say one suitable person for each borough, in one case Southwark and Lambeth to be *ex officio* on this acting committee, or to be among the acting governors, and under these an efficient secretary under the entire control of the committee, to give effect to their management.

I remain, Sir, yours, &c.,

WILLIAM RENDLE, F.R.C.S.,
Chairman of the Committee of South London Parishes,
re St. Thomas's Hospital in 1862-3.

Polperro, Cornwall, August 23rd, 1880.

TREATMENT OF CANCER.

To the Editor of THE LANCET.

SIR,—At present, when the profession are in expectation of getting a cure for this frightful disease, it has seemed to me advisable to call attention to a remedy which used to be in great vogue, but which has most unaccountably fallen into disuse. There is nothing indeed in medicine more remarkable than the fact of the way in which medicines, patent medicines too, are forgotten or thrown aside. Into the causes of this I am not now going to enter, but simply to state a well-known fact. The medicine I would now recall to notice, through your widely read pages, is the well known hemlock; and in saying this I am well aware of Harley's most valuable observations on this very drug. But it is as a remedy for cancer, in some at least of its forms, that I would here speak of it. Now, Sir, the evidence of the power of this medicine over cases of cancerous disease is very great indeed; and that man would do well to the profession who would simply make out a list of the cases where it has been so employed. Not that every case was bettered by its use, for this is not to be looked for, but that the majority were. It will be observed that I use the word “bettered;” as if I said “cured” it would be at once concluded what I advanced would not be worthy of a moment's consideration; though certainly there are plenty of cases in which a complete cure was effected; and this in cases of both what seemed open and occult cancer.

This evidence, it appears to me, seems quite sufficient to authorise us to fall back on the remedy.

It has been objected to the use of hemlock that its preparations are uncertain, and do not contain the active principle.

¹ Memoranda relating to the Royal Hospitals. Reprint, 1836.

² Reasons for Retiring, p. 21. ³ THE LANCET.

Granting that this is true, in a degree, it is certainly no reason for giving up its use. But I think that, with such a formidable disease as cancer, it would be well to use the hemlock which grows in other climates than Great Britain; for there can be no doubt that it is a much more vigorous plant abroad than amongst ourselves; and indeed the parties who first introduced it in Germany enter into particulars as to the locality in which it grows, the time of the year it is to be plucked, which prove their opinions on the matter.

The dose of the drug in common use, I may state once for all, is too small. The British Pharmacopoeia puts down the dose of the extract at from two to six grains, which is totally useless. To an adult not less than ten grains may be given; and I find a very suitable way of giving it is in an eight-ounce mixture, of which half an ounce, by measure, may be taken three times a day, each dose containing ten grains, which can be readily increased, and which will be needed in such a disease as cancer, for the dose must be pushed so as to produce its physiological effects. I speak specially of the extract as, on the whole, presenting the easiest mode of administration. It is not equal, I am aware, to the succus conii either in elegance or power; but the latter has very serious drawbacks, one being its expense, and the other the quantity of spirit which it contains. Used in the way indicated, I have found hemlock a very valuable remedy. In my hands it seems to possess two distinct effects, the first being the power of allaying pain, a matter of so much moment in cancerous disease; and the second, its restorative power on the frame, as shown by the change in the appearance of the patient; and, should there be an open ulcer, the alteration for the better in the sore. I have seen no absolute cure of cancerous disease, but I have seen several cases where the disease has been beyond question kept at bay, and the life of the patient by so much bettered.

More, Sir, could be said on this remedy, but enough I consider has been advanced to call the attention of the profession to what appears a very important subject by,

Yours truly,

Dublin.

HENRY KENNEDY, M.B.

ENTERIC FEVER IN TROPICAL CLIMATES.

To the Editor of THE LANCET.

SIR,—Kindly permit me to answer as briefly as possible the questions put by Surgeon-General Gordon in his commentary on my letter of the 31st ult.

He asks, "What is the precise sense in which the term 'enteric' is applied by the writer of that letter to the fever in India, which he describes?" In answer to this I would say that the "enteric" fever which I have observed and treated in India is "a definite disease, always recognisable after death in fatal cases by the pathological changes proper to it." This is, as it will be seen, a quotation from my own letter, in which I regarded it as an axiom that "enteric fever" (using that term as the synonym of the "typhus abdominalis" of the German school) exists in India as a specific disease, distinguished from all others by the pathological changes going on in the intestine, just as it does in temperate climates. This, however—which I must regard as a necessary premiss—Dr. Gordon would seem to deny, inasmuch as in commenting on another portion of my letter he says, "So far as the extracts from authorities and writers given in my reports justify a conclusion, that conclusion is that in fatal cases of fever due to *pythogenic* causes there are no post-mortem appearances of a nature beyond such as exist in fatal cases of non-specific fevers due to endemic and climatorial causes in India; also that appearances undistinguishable from them occur in other diseases than fever, and as results of certain poisons." This, it appears to me, amounts to saying that there is no such disease as I describe occurring in India recognisable and capable of differentiation from all other diseases by the pathological changes found in the small intestine after death, which disease is known all over the world as "enteric fever," "abdominal typhus," or "typhoid fever." If this be the opinion of Surgeon-General Gordon, it is evident that, denying, as he does, my premisses, he will not be likely to allow my conclusions. I confess, however, that I was not aware that there were any longer doubts as to the disease

which is known as "enteric fever" being pathologically as perfectly distinct in India as it is in temperate climates, nor can I understand how the position is tenable. The question, however, with which I attempted to deal was not the identity of the disease as it is observed in India and elsewhere, but, assuming such identity, to consider the question of causation. "Enteric fever" being "enteric fever," does it arise in India from climatorial causes, or is it essentially "pythogenic" in its nature? My arguments and conclusions on this point need not be repeated.

On one other point only need I touch—that is, the question of temperature as a means of diagnosis between "enteric" and "remittent" fevers. In a short paper which I communicated to the *Indian Medical Gazette* in 1877 I entered more fully into this point, upon which, in spite of Surgeon-General Gordon's criticism, I still repose the greatest confidence. I have not, unfortunately, a copy of the paper I refer to at hand.

The principal practical point is this: Given a patient who comes under our notice in the *first two days* of his illness, we can, by taking his temperature carefully night and morning, predict with almost absolute certainty, in uncomplicated cases, whether we are likely to have a case of "remittent fever"—that is, a fever of climatic origin—to deal with, or a case of "enteric." The value of this knowledge to the physician in the treatment of the disease cannot be over-estimated.

In conclusion, I trust that Surgeon-General Gordon will not consider that I offer this answer to his criticism of my letter in any dogmatic spirit. The subject is one of vast importance, and cannot be too freely discussed.

I am, Sir, yours faithfully,

Dublin, Aug. 15th.

GEO. S. RANKING, M.D. Cantab.

To the Editor of THE LANCET.

SIR,—Reading your number of Jan. 3rd, I met an article of Sir J. Fayer, M.D., on typhoid fever in tropical climates. As he wants the experience of physicians living in this climate, I take the liberty of troubling you with a few lines on the subject.

This town is situated inside of the tropical line of the south, and is two degrees south of Rio de Janeiro, Brazil. Here I have observed, in a year, nine cases of typhoid fever in persons from twelve to thirty-five years of age—five males and four females (eight white and one mulatto).

They all had fever from twenty-one to twenty-five days. Most of them had epistaxis, and one almost died from its severity. They had diarrhoea, some from the first, others from the seventh day, and more than half had severe intestinal hæmorrhage, requiring the energetic use of astringents.

There are physicians here who deny the existence of typhoid in this country, but I have seen many cases of this fever in the hospitals in Paris, London, and in the United States, and I find no difference between the fever treated there as typhoid and the cases I have seen here among the natives of this country.

The duration of the fever (twenty-one to twenty-five days), the general appearance of the patients, the epistaxis, the rose-coloured spots on the abdomen, the tenderness and gurgling in the right iliac fossa, the dryness of the tongue, the deafness, muscular pains, circumscribed flush on the face, sordes on the teeth, dryness of skin, pulse 100 to 120, debility, somnolence, mental confusion, and other symptoms resemble the typhoid fever of the countries north of the tropical line.

I am sorry in not being able to furnish the thermometric observations of these cases, for the patients were country people, living in farms, where it is impossible to keep daily observations of the patients, but I can assure you that from the fourteenth day the temperature generally fell.

In none of these cases did I give a grain of quinine. In the first stage, when the fever is high, I give ordinarily small doses of nitrate of potash, and in the last stage preparations of bark, alcoholic stimulants, Todd's solution, and externally linseed poultices and turpentine fomentations. No purgative is given, except in the first five days, when there is constipation. I do not allow any solid food, but give milk, beef-tea, coffee in small doses and frequently. Out of the nine patients I observed last month and part of this, eight are living, and well, and one died thirty-six days

after recovery, from eating cheese and a large piece of beef, probably producing intestinal perforation.

These cases are observed here in the last part of summer, which in Brazil ends in March and April.

I cannot give the precise cause of the fever here, but attribute it to decomposition of organic substances in some cases.

Two of the cases I treated were nurses who attended my typhoid patients and fell in sickness after their recovery. Most of them were living in isolated farms, where typhoid was never observed before, though Dr. Budd believed that this fever only originated from the stools of individuals affected with the fever.¹

The typhoid or enteric fever described by Murchison, Tanner, Niemeyer, Trousseau, Flint, Wood, and other European and American writers, and the cases I have observed here, are very similar.

I have no doubt they are cases of typhoid, and the treatment I use having produced good results, proves the correctness of my diagnosis.

I am, Sir, yours faithfully,

G. PIZA ALMEIDA, M.D.

Itatiba, Province of Sao Paulo, Brazil, March 20th, 1880.

PRELIMINARY EDUCATION.

To the Editor of THE LANCET.

SIR,—Although, as you have pointed out, elementary medical education is not a fit subject for interminable revision by the Medical Council, it is still a fit subject for continued discussion by the profession in general. Holding this opinion, I venture to express my views with regard to the subjects best suited for the preliminary examinations. If we consider the great amount of biological and physiological knowledge acquired in recent times, the importance and extent of our gains in various departments of science, the clear conceptions of force and energy which may now be commanded; if further we consider the importance of all these to a reflective practitioner, we should hesitate to debar him from attaining them by compelling him to useless toil. Of what possible use to him can be a smattering of Greek or Latin? Is it to be supposed for a moment that elegance of address or refinements of speech or thought entangle themselves in the pages of a Latin or Greek grammar; that a laborious effort to read the *Anabasis* of Xenophon gives him the culture which is supposed so needful? Could he even read the plays of Sophocles, might he not gain more from the dramas of Shakespeare? from his lyrics than from the Choral Odes of the older poet? Is there any prose literature to compare with our own? But, surely, if he acquires foreign languages at all they should be the modern German and French, so that he may be able to read their scientific works and make himself familiar with contemporary thought.

It is hardly too much to say that to compel a student entering on his medical career to obtain an imperfect acquaintance with the ancient languages, aware that what he has learned will forthwith be forgotten, is to give him an aversion to labour which will most likely spoil the earlier years of his work, and will certainly start him on a false method of gaining knowledge.

It seems to me that false conceptions exist as to "culture," and that "culture," as understood at present, is somewhat contemptible. The culture that a man wants is that which will enable him at least to understand the main advances in his profession, and, if it is in him, to give his aid to them.

Insight into character, sympathy of nature, and refinement are, in the main, neither acquired nor acquirable by any polishing machine. What we want in these times is that men entering the profession should be more or less familiar with "the new learning" of our time. They should know their own language and German and French sufficiently well to read works in these languages. They should also know the facts which will come prominently before them in chemistry, mechanics, dynamics, hydro-mechanics, electricity, heat, and sound, and such knowledge should be limited, practical, and thorough. In the same way they should know something of biology and physiology in a prac-

tical sense as a preparation for their after-study on a large scale.

A new world is springing up around us. The heroism and poetry of our time is scientific. In *Lebensfluthen im Thatensturm* the greatest minds are tracking the path of the *Erdgeist*. The intellectual national life is everywhere pressing forward more strongly to further knowledge of the material world and its wonders. Here lies our modern El Dorado. In this movement the medical profession must share largely. The fundamental facts of living protoplasm and the various stages of living matter illustrate themselves in the body of man. The interdependence of the animal functions in general, and of the mental processes in particular, with the nervous system, is receiving and demanding a closer and more extensive study. The applications of heat and electricity to health and disease necessitate some knowledge of these sciences. Illustrations might be indefinitely multiplied. But inasmuch as it is of equal, if not of greater, importance that a man should begin his life study comparatively fresh, able, and willing to work, the amount of these various sciences taught should be only what is essential. What we want is not barren discussions about the exclusion or retention of Greek or Latin, which must soon disappear, but an effort to arrange the essentials of scientific knowledge, disencumbered of unnecessary detail, so that they may readily come within the range of schools and the reach of young men about to enter the medical profession.

I am, Sir, yours obediently,

J. NIVEN, M.B.,

Deptford Hospital.

Fellow of Queen's College, Cambridge.

* * In accordance with our motto, we print the above letter, though, as our correspondent will see by reference to another column, our views differ somewhat from those he has here advanced.—ED. L.

"A CHEMICAL LUNG."

To the Editor of THE LANCET.

SIR,—As you thought my suggestion for purifying collections of foul air by chemical means worthy of notice in THE LANCET, perhaps a more detailed account of the scheme may not be unacceptable. Caustic alkalies are well-known to possess great affinities for carbonic acid and sulphur gases. In the case of the Underground Railway I propose to add a special chamber to each train—say a disused third-class carriage, open at each end, and so constructed that, by the aid of wings and 'chutes, it shall occupy as large a sectional area of the tunnel as is possible. Trays carrying caustic lime, kept moist by a tank of water on the roof or otherwise, occupy the whole interior space of the carriage, which may be placed either at the rear of the train or next the engine. Instead of trays carrying the alkali, in a solid or semi-solid form, sheets of canvas or other suitable material may occupy their place, and, by means of a reservoir of caustic soda above, be constantly kept wet, the surplus fluid being collected in a lower tank, whence an automatic pump, connected with the wheel of the chamber, pumps it up, to fall again through the sheets. Charcoal stacks may take the place of the sheets; the stacks made in frames easily handled, of fine branches arranged in crossed tiers, and kept constantly wet, as in the case of the canvas sheets. Again, a series of water-wheels, constructed of canvas or other suitable material, with rims dipping into a lower tank of caustic soda, and so formed as to carry up the fluid and pour it over their surfaces, the current of air as it rushes through the chamber sufficing to cause the wheels to revolve, and so to expose a surface, constantly wet with the chemicals, to the action of the air; and when the train passes into the open the wheels may be skidded, and so unnecessary waste of chemicals be avoided.

If a special carriage be considered impracticable, as some think, then an exhausting fan may drive the gases of the smoke box direct into a tank filled with the chemical solution, and the carbonic oxide which will issue, freed from other gases, may be converted into carbonic acid, either by causing it to pass through a tube under the ashpans of the furnace or else over a spirit or gas flame; or, again, electricity, evolved either by the friction of the train or by a special battery, may be called into requisition for the same purpose—viz., the conversion of the carbonic oxide into carbonic acid.

A punkah, constructed upon chemical principles, will, I

¹ It was perfectly well known to Dr. William Budd that nurses, or even medical men, in attendance on typhoid patients, might contract the disease in removing or inspecting the stools, and, having contracted, spread it, without being themselves attacked with fever, although probably suffering from slight *malaise*.—ED. L.

think, be found most useful in sick chambers, small rooms, and offices, and, if sufficiently large, at the stations of the Underground Railway, should it be necessary to purify the large volume of air that will not enter the chamber after it emerges from the tunnels. An eminent firm in London is constructing these punkahs, and hope soon to have them on public view. In theatres and other large buildings it is proposed to have one or more intakes in the roof, or elsewhere, connected by hose or tubes, with a sufficiently powerful exhausting fan in the basement of the building; the foul air from above is then driven through a tank, or other form of chemical lung, and allowed to escape and find its way back again to the upper part of the building, being cooled, if need be, or oxygen added if desirable. The application of this principle to the purification of the air in Turkish baths, and also to destroy any noxious gases emanating from cremation furnaces, is self-evident. Many have been the views taken of each individual portion of the scheme; experience alone can test its strong and weak points. As regards the Underground Railway, a few hours would be sufficient to form a decided opinion; with a single lung, the air, on entrance and exit, being analysed, would at once show the amount of foul gases passing through and destroyed in a given time and space. The necessary amount of alkali per train could then be easily calculated.

I am, Sir, yours, &c.,

RICHARD NEALE, M.D. Lond.

Boundary-road, S. Hampstead, Aug. 21st, 1880.

"INFLAMMATORY AFFECTIONS OF THE JOINTS IN CHILDHOOD."

To the Editor of THE LANCET.

SIR,—In a clinical lecture by Mr. Howard Marsh, on "The Treatment of Chronic Inflammatory Affections of the Joints in Childhood, with especial reference to Excision," which appeared in THE LANCET of July 31st, he points out in a very able manner the advantages of the treatment by rest and the use of leather splints, in which I entirely agree with him. He says, however, that many cases come under his notice of deformity as the result of other forms of treatment, and he asks the question: "Is surgery unequal to the treatment of these distorted joints—are not these just the cases for excision?" and in answering this question he says: "I grant these, if any, are the cases for which excision is appropriate; cases, that is, in which there is little or no disease, but much distortion. But the point is that you excise a joint not because it is the seat of incurable disease, but because it has been allowed to get out of shape. Prevent the deformity and the necessity for excision vanishes."

Now, in this I venture to think Mr. Marsh is in error, and the question should rather be answered thus:—Very many of these cases of deformity for which, in Mr. Marsh's opinion, excision is appropriate, and especially those affecting the knee and ankle, can be rectified by gradual extension after tenotomy, sometimes with a stiff joint, and in other cases with more or less motion, according to the extent of the original disease. From the number of contracted joints that have come under my notice, and which have been successfully treated by this method, I infer that the value of this mode of treatment is not sufficiently recognised.

I am, Sir, yours faithfully,

HENRY F. BAKER.

Hanover-square, August 3rd, 1880.

LEATHER STRAPS v. BANDAGES.

To the Editor of THE LANCET.

SIR,—The liability of bandages and slings, when required to bear any strain to stretch and ruck, must be generally recognised. This disadvantage is particularly noticeable when treating a fracture of the clavicle or acromion process. Mr. G. Cardy Edwards of Ipswich, fifty years ago, met this disadvantage in fracture of the clavicle by the use of a couple of round leather straps, with an oval pad with a buckle on it at one end, and holes at the other. These straps he applied as an ordinary figure-of-eight bandage, either pad being in front of either shoulder. The coolness, comfort, and firmness of these clavicle straps have induced me to keep and use them for the past twenty years.

Last winter the horse of the whip to the Duke of

Hamilton's harriers, while galloping across a ploughed field, placed its feet into a water furrow, threw the whip, and, in rolling over, struck his acromion with the edge of the back of the saddle and fractured it. I put it up in the ordinary way, with sling, pad, and bandage. At the end of forty-eight hours I was dissatisfied with its firmness, and thought possibly the frequency of fibrous union in these fractures might be due to the difficulty of keeping the ends in perfect apposition. I discarded the sling and bandage, and used the clavicle straps. One pad I placed under the elbow, and the other on the proximal side of the fractured acromion, and tightened the straps till the ends of the fracture were in perfect position. I had put a second buckle on the acromion pad, to which I fastened one end of a round leather strap, and carried it across the back, under the arm, and up in front of the chest, and fixed the end in the same buckle. The ordinary pad and the arm were kept to the side by another strap round the chest. Everything kept in perfect position. The clavicle straps brought the ends of the fracture quite close, and the second strap from the acromion pad made him, as he expressed it, "feel quite whole."

The coolness, firmness, and sense of security given by the leather straps, I think, ought to lead to the sling and bandage being discarded in their favour.

I am, Sir, your obedient servant,

Framlingham, Aug., 1880.

GEO. E. JEAFFRESON.

CASE OF COIN-SWALLOWING.

To the Editor of THE LANCET.

SIR,—Perhaps you may think it worth while to publish the following case as exemplifying the treatment alluded to in your number of July 31st, in a case of a child swallowing the tongue of a bell:—

A man, aged fifty-one, of rather irregular habits, swallowed three sovereigns at a gulp for the wager of a pot of beer. The next morning, being in a more thoughtful frame of mind, he consulted me as to what was best to be done, feeling apprehensive as to the result of the previous evening's folly. I directed him to eat as much solid food as possible, avoiding superfluous fluids. The fear of impending mischief seemed to stimulate his appetite, for he carried out my advice in a wonderful manner. In twenty-four hours he was rewarded by hearing the merry chink of his three sovereigns once again in his pocket. He had holes bored in his coins; one he wears appended to his watch-chain, perhaps to remind him of his foolhardihood, another he presented to a friend, who wears it in the same way, and the other was, I believe, exchanged to the loser of the wager for one which had not passed through the same unusual experiences.

I have frequently had occasion to advise eating, to the full, solid food in cases where foreign substances have been swallowed, and I cannot call to mind a single instance in which such treatment, when adopted immediately, failed to carry off the offending body. Although I have never seen an instance of fatal termination in any such cases where purgatives have been at once administered, I do know of some where prolonged anxiety and pain have been occasioned by such treatment, notably in the case of a woman who swallowed a date stone, and hoped to rid herself of it by immediately taking a dose of castor oil. This patient suffered considerable pain about the neighbourhood of the duodenum, striking through to the back, increased after eating, and sometimes accompanied with great anxiety and some feverishness. This condition lasted for many weeks, and only subsided very gradually.

Faithfully yours,

JAMES WORTHINGTON,

Surgeon to Lowestoft Hospital.

July 31st, 1880.

PARIS.

(From our own Correspondent.)

THE pestilential smells which have infested Paris for some time are awakening a feeling of indignation against the responsible authorities, which is expressed freely in the daily papers, and that quite independent of party spirit. A few days since, the well known critic, Francisque Sarcey, devoted an article to this matter in the *Dix-Neuvième Siècle*, and

invited the inhabitants of his district to sign the petition in preparation against the nuisance; and the *Figaro* of to-day prefaces some satirical remarks by the statement that "Paris est en ce moment infecté par les odeurs les plus épouvantables. Tous les égouts sont à découvert." The odours, which in reality emanate, as was stated in a previous letter, from the night-soil *depotoirs* which surround the city, and also from the carts and boats which convey the sewage outside the walls, are due to the neglect of the contractors in the use of disinfecting measures, and there seems to be no doubt about the connivance of the police at this abuse. M. Sales Roche, one of the most energetic of the municipal councillors in sanitary matters, has written a letter to the Prefect of Police announcing his intention of questioning him upon the subject when the Council resumes its sittings. He states that the day after the discussion, which took place about a month ago, the air of Paris was pure and respirable; but as soon as the holidays commenced, the smells made their reappearance worse than ever. "We cannot all," says M. Roche, "go to the seaside. Many, after a hard day's work, wish for a breath of fresh air in their evening walk. But at this hour the town is 'empoisoned.' Your administration has tolerated for months an abuse which would not be suffered for the space of twenty-four hours in the most obscure village in France." The *Petite République Française* thinks that the only remedy lies in the suppression of the bureaux, which are fallaciously called "sanitary," or "hygienic," and which cover the responsibility of the Prefect by a semblance of official sanction, which, as a matter of fact, they cannot withhold.

An operation of considerable interest was recently performed at the Beaujon Hospital by M. Tillaux. A man, aged thirty-one, had enjoyed good health until the 25th of last May, when he was suddenly seized with the most violent pain in the abdominal region. In spite of all treatment the pain continued; and after suffering for some days the patient applied to the out-patient department of the Lariboisière Hospital, where it was found that he had a tumour, which was supposed to be a floating kidney. For more than a fortnight he remained without any further advice, having intermittent attacks of pain, which lasted for some time, unable to eat or lie down without provoking an attack, and obliged to sit doubled up with chin on his knees. He then consulted Dr. Millard, physician to Beaujon, for his "floating kidney," who admitted him into the hospital for this affection, changing, however, the diagnosis after a time to that of chronic intestinal invagination. Continuous currents and rectal douches were tried for a time without any result, and finally, at the urgent request of the patient, it was determined to perform the operation of gastrostomy. The abdomen wall was incised by M. Tillaux with strict antiseptic (Listerian) precautions, and the hand being introduced into the cavity, a tumour the size of the head of a fetus was discovered, springing from the mesentery. An exploratory puncture giving no information as to its nature, it was freely incised, and found to consist of a cyst filled with caseous matter. The pedicle having been tied with catgut, the tumour was removed, and the stump returned after being washed with a strong solution of carbolic acid. Two days later there were threatening symptoms of peritonitis, but these passed off, and a perfect recovery ensued. The growth turned out to be a cyst which had developed in one of the mesenteric ganglia.

Paris, August 25th.

MEDICAL NOTES IN PARLIAMENT.

IN the House of Commons on Thursday, the 19th inst., the following papers were laid upon the table by the Clerk of the House:—Abstracts of the quinquennial returns of sickness and mortality experienced by Friendly Societies for the periods between 1855 and 1875; and abstracts of accounts for 1879 of English and Welsh county and borough lunatic asylums.—Mr. John Talbot gave notice of a question with regard to the drainage of that part of Westminster in which the public offices are situate.

On Monday, in reply to Mr. A. O'Connor, Mr. Mundella stated that the Crown nominees on the Medical Council were appointed by Her Majesty in Council, for a term not exceeding five years, in accordance with the provisions of the Medical Act of 1858. Section 8 of that Act provided that any person so nominated might at any time resign his

appointment by letter addressed to the President of the Medical Council.

On Tuesday the statistical report of the health of the navy for the year 1879 was presented. The following notice was given for next week:—Mr. Firth,—"To ask the Under Secretary of State for the Home Department whether he is aware that during the month of July last the Fishmongers' Company ordered the destruction of more than ninety tons of fish as being unfit for human food; that this loss was mainly due to the utter inadequacy of the fish market accommodation in London. Whether he is aware that such inadequacy arises from the fact that no new market can be established within seven miles of the City of London without the consent of the Corporation of London, and that the Corporation claim to prevent and have repeatedly prevented such establishment. And whether, having regard to the fact that this claim is founded upon charters granted at a time when the limits of the metropolis were co-terminous with the City, the Government are prepared to advise the cancellation of such charters and to support any measure introduced by the Metropolitan Board of Works, or other responsible authority or persons, for the establishment in London of markets for the people."

On Thursday, in reply to Mr. Beresford Hope (on behalf of Mr. Talbot), Mr. Adam said his attention had been called to an article in the *Builder*, in the heading of which some reference was made to the Government offices, but the article itself dealt with the main drainage system of Whitehall and Westminster. That was not under the jurisdiction of the First Commissioner of Works, and any application on the subject should be made to the Metropolitan Board.

Obituary.

PROFESSOR DR. FERDINAND R. v. HEBRA.

WE briefly chronicled in our columns lately the loss the Vienna School of Medicine had sustained in the death of Dr. Ferdinand R. v. Hebra, a professor whose fame was recognised throughout the civilised world. The death of one who exercised such influence on the branch of medicine which he made his specialty should not be allowed to pass without a record of his personal career, or an attempt to define the position he held in dermatology.

Hebra was born on the 7th September, 1816, at Brünn, and acquired his medical education at Vienna, where he obtained his doctor's degree in 1841. For awhile he turned his attention more particularly to surgery, but, before long, devoted himself to medicine under the illustrious Skoda, in whose department skin diseases were included, but without any effort at specialisation or organised treatment. Feeling strongly the unsatisfactory condition of this branch of medicine in Germany, both as regards its scientific position and the way it was taught, and recognising in Hebra an ability thoroughly fitted by its acuteness and zeal to deal with the subject, Skoda induced him to enter on the study of diseases of the skin; and the result was, in 1842 (the year of issue of the first edition of Erasmus Wilson's large work), the delivery of a private course of lectures by Hebra, which attracted considerable attention. The first step gained, his next object was to induce the authorities to found a special department for skin diseases. This, after much opposition, and chiefly by the influence of Skoda, he succeeded in achieving, thus enabling him to command ample material for his subsequent labours, as well as drawing a large number of students, by his masterly exposition of an intricate and ill-understood subject.

At this time, through the labours of Alibert, Biett, Gibert, Cazenave, Schedel, and Rayer, the Hôpital St. Louis in Paris was really the only School of Dermatology, and the influence of its professors was paramount. To appreciate Hebra's influence, it is also necessary to understand that at this time there was much disagreement on fundamental points between French and English writers; the nomenclature had grown intolerably cumbrous and unintelligible, and the whole study, notwithstanding Willan's great work and the fruitful and valuable labours of many French observers, was in a most unsatisfactory condition. As Hebra laboured on through the succeeding years he gradually tested all that had been previously written by means of his own

abundant material and accurate observation and comparison, sifting the wheat from the chaff, till he placed dermatology on a thoroughly scientific basis, and established sufficient facts to form a sure foundation for the labours of succeeding observers. He also did good work in simplifying the nomenclature, and classified skin diseases in accordance with the views of his colleague Rokitsky on an anatomico-pathological basis. Meanwhile, the extremely logical character of his writings, and his lucidity and capacity as a teacher, were widely extending his reputation, and increasing crowds of students from all lands attended his clinique in the rising Dermatological School of Vienna in preference to the celebrated Hôpital St. Louis. From America especially great numbers constantly attended his lectures, and Hebra's influence in stimulating research amongst his pupils and placing the study of skin diseases in its present position in that country is very remarkable.

In addition to his lecturing and teaching capacity, the quality of his writings, his influence in the extension of knowledge, his scientific reorganisation and simplification of the subject, and the foundation of a great school, which has eclipsed all others, we should mention the masterly way in which he observed several affections hitherto unrecognised as possessing special features, his endeavour to encourage the pathological study of dermatology, and the additions he made to our resources for the local treatment of disease, in the way of baths, caustics, soaps, and so on.

Although Hebra recorded the results of his incessant labours from time to time on a great variety of dermatological subjects, his greatest work is that on "Diseases of the Skin," translated by the Sydenham Society. He also published a well-known Atlas of Skin Diseases, and wrote the chapters on the Special Pathology and Therapeutics of Skin Diseases in Virchow's Handbook, besides editing for ten years the Proceedings of the Medical Society of Vienna.

For many years the professor enjoyed an enormous practice, for his fame attracted patients from afar, and his literary labours had been lightened by the eminent services of Professor Kaposi, who assisted him with the later volumes of his great work. Hebra's health had for some time been failing, and awaiting his end with much resignation, he died, full of honours bestowed by the medical profession in Vienna and by the Imperial Government, on August 5th, leaving a widow and five children. The eldest of his three sons is the well-known writer on skin diseases in Vienna, Hans Hebra, and one of his daughters is married to Professor Moriz Kaposi. The admiration felt for his talents and services to science, and the reverence with which he was regarded by his pupils and colleagues, were shown on more than one occasion during his lifetime, and at his funeral, which he desired to be very quiet, there was a large and respectful gathering to pay a last tribute to the memory of the illustrious professor.

Medical News.

UNIVERSITY OF LONDON. — The following candidates have passed the recent First B.Sc. and Preliminary M.B. (conjoint) Examination for Honours in the subjects indicated:—

CHEMISTRY.

FIRST CLASS.

Stroud, Wm., First B.Sc. (Exhibition), Owens College.
*Gee, Wm. Winson Haldane, First B.Sc., Owens College.
*Roberts, Thomas, First B.Sc., Birmingham and Midland Institute and private tuition.

SECOND CLASS.

Ledlie, Wm., First B.Sc., Christ's College, Cambridge.
Beverley, Richard Joseph, First B.Sc., private study.
Kensington, Arthur Hayes, First B.Sc., Royal School of Mines and University College.

THIRD CLASS.

Irwin, Wilfred, First B.Sc., Owens Coll. and priv. study.
Hart, Herbert Wheatley, Prel. Sci., Westminster and Guy's and Birkbeck Institute.
Fison, Alfred Henry, First B.Sc., Royal School of Mines.
Read, Alfred John, B.A., First B.Sc., Univ. of Edinburgh.
Edmunds, Percy Jas., Prel. Sci., University College.
McCabe, W. Alex. Bowes, Prel. Sci., University College and Victoria Coll. Jersey.
Walmsley, Robt. Mullineux, First B.Sc., private study.
Fowler, Alfred Henderson, Prel. Sci., Guy's Hospital.
Eiloart, Arnold, First B.Sc., private tuition.
Andrews, Edw. Collingwood, Prel. Sci., University College.

Snape, Henry Lloyd, First B.Sc., Owens College.
Cave, Edward John, Prel. Sci., St. Barthol. Hospital.
Macartney, Ed. Kendrick, Prel. Sci., University College.
Walker, Thos. Hollis, First B.Sc., Epsom College.
Thompson, Francis Clement, First B.Sc., private study.
Kimmmins, Chas. Wm., First B.Sc., Owens College.
Eves, Florence Elizabeth, First B.Sc., Newnham Hall, Cambridge.
Todhunter, Wm. Alfred, B.A., First B.Sc., private study and tuition.
Anderson, G. Elliott Caldwell, Prel. Sci., South African College and Guy's Hospital.
Wallace, Robt., First B.Sc., private study and tuition.

EXPERIMENTAL PHYSICS.

FIRST CLASS.

Turner, H. H., First B.Sc., Arnott Exhibition and Medal, Trinity College, Cambridge.
Stroud, Wm., First B.Sc., Arnott Medal, Owens College.

SECOND CLASS.

Edmunds, Percy Jas., Prel. Sci., University College.
Sutherland, William, First B.Sc., University College and private study.
Innes, Chas. Barclay, Prel. Sci., University College.

THIRD CLASS.

Allen, Henry, Prel. Sci., private study.
Gee, Wm. Winson Haldane, First B.Sc., Owens College.
Catchpool, Ed., First B.Sc., Roy. Polytechnic Institution.
Ledlie, Wm., First B.Sc., Christ's College, Cambridge.
Cave, Edw. John, Prel. Sci., St. Barthol. Hospital.

BOTANY.

SECOND CLASS.

Eves, Florence Elizabeth, First B.Sc., Newnham Hall, Cambridge.
Pearson, James, Prel. Sci., University College.

THIRD CLASS.

Brock, Jas. Harry Ernest, Prel. Sci., University College.
Earle, Walter Geo., Prel. Sci., University College.
Freeland, Freeland John, Prel. Sci., King's College.

ZOOLOGY.

FIRST CLASS.

Spencer, W. Baldwin, Prel. Sci. (Exhibition), Old Trafford School and Owens College.
*Jones, Samuel Cromwell, Prel. Sci., University College.

SECOND CLASS.

Eq. { Brock, Jas. H. Ernest, Prel. Sci., University College.
{ Thane, Edgar Herbert, Prel. Sci., University College.
Adam, John Geo., Prel. Sci., Old Trafford School and Owens College.

THIRD CLASS.

Arkle, Chas. Joseph, Prel. Sci., University College.
Eq. { Chapman, Harry Cecil, Prel. Sci., St. Barth. Hosp. and Royal School of Mines.
{ Edmunds, Percy Jas., Prel. Sci., University College.

* Obtained the number of marks qualifying for the Exhibition or Prize.

BRITISH MEDICAL SERVICE. — The following is a list of the candidates for appointments as Surgeons in the above Service who were successful at the competitive examination in London on Aug. 9th:—

Marks.	Marks.
S. A. Crick 2510	L. W. Swabey 1610
J. R. Dodd 2240	R. Haselden 1605

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on Aug. 19th:—

Cooper, Walter, George-street, Croydon.
Davis, William Henry, Newcastle-on-Tyne.
Divecha, Kalkhasov R., Bombay.
Lunn, Ernest Craven, Hull.
Reynolds, John Swatman, Upper Norwood.
Symons, George Francis, Stockwell Hospital.
Watkins, Christopher James, Mornington-road.

The following gentlemen also on the same day passed their Primary Professional Examination:—

Henry Settle, St. Bartholomew's Hospital; Charles Arthur Wigan, Charing-cross Hospital; Joel Harrington Douty, Middlesex Hospital; John W. Lynch and Arthur Knight Gale, London Hospital; Edward H. McLaughlin, St. Thomas's Hospital; Thomas Russell Pickthorn, St. George's Hospital; Peter Pigott, Guy's Hospital.

[The fourth name in our list of last week should have been printed "Oswald," not "Oswold."]

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—Upwards of 500 candidates have entered their names for the forthcoming preliminary examination in arts, &c., for the diploma of Member or Fellow of the Royal College of Surgeons of England, being the largest number on record. Cards of admission, with a time-table, will be forwarded to each candidate in the course of a day or two. The examination will commence on Tuesday, September 7th, at 9 o'clock A.M., at the University of London, Burlington-gardens, W.

A CONVALESCENT HOME is to be founded at Bexhill-on-Sea, at a cost of £12,000, with accommodation for a hundred patients. A sum of £6500 has been contributed by one donor towards the building.

MR. MACRORY, late honorary secretary to the Belfast Royal Hospital, has been presented with an illuminated address, in recognition of his services in connexion with the hospital during the past forty-seven years.

THE BRITISH PHARMACEUTICAL CONFERENCE, held this week at the Royal Institution of South Wales, Swansea, appears to have been well attended. Mr. W. Southall, of Birmingham, the President, delivered an address on the Pharmacy of Celsus and many later medical writers.

BEQUESTS ETC. TO MEDICAL CHARITIES.—Mr. Edward Pease bequeathed £1000 to the Saltburn Convalescent Home. By the will of Mr. William Fisher, late of Sheffield, the Sheffield Infirmary and the Hospital for Women, Figtree-lane, become entitled each to £250. The Right Hon. Joseph Chamberlain M.P., and Messrs. J. T. Chance, Thomas Gladstone, T. Kenrick, William Middlemore, and A. F. Osler, have each given £100 towards the proposed new Ladywood Branch of the Birmingham General Dispensary.

Medical Appointments.

Intimations for this column must be sent DIRECT to the Office of THE LANCET before 9 o'clock on Thursday Morning, at the latest.

ANNINGSON, B., M.D., M.R.C.S.E., has been reappointed Medical Officer of Health for the Borough of Cambridge. £250 per annum.
BARNES, H., M.D., has been appointed Consulting Physician to the Cumberland and Westmorland Convalescent Institution at Silloth.
DAVIES, J. W., L.R.C.P.L., M.R.C.S.E., has been appointed Medical Officer for the Clun District of the Clun Union, Shropshire.
EWART, W., M.B., M.R.C.P.L., has been appointed Pathologist and Curator of the Museum of the Hospital for Consumption and Diseases of the Chest, Brompton.
GLASCOTT, C. E., M.D., has been appointed Honorary Oculist to Henshaw's Blind Asylum, Old Trafford, Manchester.
JOHNSTONE, J. C., M.B., C.M., has been appointed Assistant-Physician to the Royal Edinburgh Asylum, Morningside.

KEYWORTH, G. H., M.B., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer for the Wem District and the Workhouse of the Wem Union, vice S. B. Gwynn, F.R.C.S.E., L.S.A.L., deceased.

LOGAN, F. T. B., M.R.C.S.E., has been appointed Medical Officer for the First (A) District and the Small-pox Hospital of the Westminster Union.

MACINTYRE, A., M.B., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer for the Parish of Ardochattan and Muckairn, Argyllshire.

MASSON, W. H., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer for Districts Nos. 1 & 2 and the Workhouse of the Daventry Union.

MITCHELL, R. B., M.B., C.M., has been appointed Assistant-Physician to the Fife and Kinross District Asylum, vice Johnstone.

MOORE, Mr. E. H., has been reappointed Public Analyst for the Eastern Division of Sussex for one year. £50 and fees.

MORGAN, W., F.C.S., has been appointed one of the Public Analysts for the County of Glamorgan. 10s. 6d. for each analysis, and £2 12s. 6d. for each statutory report to Quarter Sessions.

PARKER, W. R., B.A., M.B., has been appointed Resident Medical Officer to the Fever Hospital, Netherfield-road, Liverpool.

PATTINSON, J., F.C.S., has been appointed Public Analyst for the Borough of Gateshead. £100 per annum.

PULLIN, F. B., L.R.C.P.Ed., L.F.P.S.G., has been appointed Medical Officer for the Churchstanton District of the Taunton Union.

REDWOOD, T., Ph.D., has been reappointed Public Analyst for the Parish of St. John and St. James, Clerkenwell, for one year. £100 per annum.

RIDDELL, R., L.R.C.S.Ed., has been appointed Medical Officer for the Cheriton Bishop District of the Crediton Union.

THOMAS, E. G., M.B. & C.M., has been elected Second Assistant Medical Officer to the Gloucester County Asylum.

THOMAS, J. W., F.C.S., has been appointed one of the Public Analysts for the County of Glamorgan. 10s. 6d. for each analysis, and £2 12s. 6d. for each statutory report to Quarter Sessions.

THOMPSON, R. E., M.D., F.R.C.P.L., has been appointed Physician to the Hospital for Consumption and Diseases of the Chest, Brompton.

THURNAN, F. W., M.B., C.M., has been appointed Medical Officer and Public Vaccinator for the Brafeld District of the Hardingsstone Union, vice H. Arnold, resigned.

WANOSTROCHT, V., M.B., C.M., has been appointed Medical Officer to the Escrick District of the York Union.

Births, Marriages, and Deaths.

BIRTHS.

BOWES.—On the 12th inst., at Berry Wood, Northamptonshire, the wife of J. Ireland Bowes, M.R.C.S.E., of a son.

JULER.—On the 22nd inst., at Wimpole-street, Cavendish-square, the wife of Henry Juler, Esq., F.R.C.S.E., of a son.

NORBURY.—On the 27th ult., at Simons Town, Cape of Good Hope, the wife of Henry F. Norbury, C.B., Fleet-Surgeon, R.N., of a son.

ORAM.—On the 19th inst., at Clapham-common-gardens, S.W., the wife of Richard R. W. Oram, L.R.C.P.L., M.R.C.S.E. (prematurely), of twin daughters.

PEACOCK.—On the 24th inst., at Forston House, near Dorchester, the wife of Henry Geo. Peacock, L.R.C.P., M.R.C.S.E., Assistant Medical Officer to the Dorset County Asylum, of a son.

ROSSITER.—On the 20th inst., at Cairo Lodge, Weston-super-Mare, the wife of George Frederick Rossiter, M.B., of a daughter.

SMITH.—On the 22nd inst., at Carlton House, Pembridge Villas, Bayswater, the wife of E. Stanley Smith, M.R.C.S.E., of a son.

WALLACE.—On the 22nd inst., at 243, Hackney-road, E., the wife of Frederick Wallace, L.R.C.P.L., of a son.

WILLMOTT.—On the 15th inst., at Bayswater, the wife of Julius J. E. Willmott, M.D., of a son.

MARRIAGES.

BARTLEET—KEMP.—On the 18th inst., at the Parish Church, Castleford, by the Rev. W. T. M. Sylvester, Rector, assisted by the Rev. J. J. Needham, Rector of Whitwood Mere, Harold Stock Bartleet, eldest son of Robert Smith Bartleet, Esq., J.P., D.L., of The Shrubbery, Redditch, to Edith Elizabeth Kemp, eldest daughter of Ebenezer Walker Kemp, Esq., M.R.C.S.E., L.S.A.L., of Bridge Foot, Castleford.

DAVEY—LANG.—On the 17th inst., at Christ Church, New York, Francis Albert Davey, M.R.C.S.E., younger son of the late William Davey, Esq., of Lyncombe, Bath, to Sara Emily, second daughter of Thomas Lang, Esq., of Langville, Georgia, U.S.A.

DUKE—MAY.—On the 14th inst., at St. James's, Clapham-park, Benjamin Duke to Annie Langford, only daughter of Robert Charles May, C.E., of Clapham-park, and 6, Great George-street, Westminster.

TODD—SCOTT.—On the 14th inst., at St. George's, Tombland, Norwich, by the Rev. Kirby Trimmer, Octavius Todd, M.B. & C.M., Surgeon, Army Medical Department, of Landour, Himalayas, India, to Kathleen Mary, second daughter of the late Robert Bagge Scott, of Norwich.

DEATHS.

BRIMS.—On the 13th inst., at Pitlochry, N.B., Elizabeth, relict of the late James Brims, M.D., of Mount Villa, Burnley, aged 48.

HEYWOOD.—On the 18th inst., at Pendleton, H. J. Heywood, M.R.C.S.E., aged 45.

KNOWLES.—At Newmarket-road, Cambridge, Edward Knowles, M.R.C.S.E.

THEED.—On the 20th inst., at The Vicarage, Lower Halstow, Kent, the residence of his brother, Frederick Theed, F.R.C.S., formerly of Rhyll, aged 66.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

METEOROLOGICAL READINGS.

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET to be addressed "To the Publisher."

THE STUDENTS' NUMBER OF THE LANCET

will be published on Saturday, September 11th. Those gentlemen holding official situations connected with Medical Institutions in the United Kingdom, who have not yet forwarded the necessary information to our Office for publication in that number, are earnestly requested to send it *without the delay of a single post*.

A DISCLAIMER.

WE have received a communication from Dr. James Greenwood, M.R.C.S., of 48, Canonbury-square, disclaiming the authorship of a paper, entitled "A Case of Fatal Ulceration of the Duodenum, produced through Scalding by Hot Water used as a Hæmostatic, by J. R. Greenwood, M.R.C.S.," which appeared in our last number. Dr. Greenwood says, "I know nothing whatever about it. I have never sent any particulars to THE LANCET Office, nor did my son."

Twyford, Berks.—Dr. Coumbe should address his question to the Clerk, or to the Board of Guardians, who will no doubt give him the necessary information concerning the circumstances under which the Board (acting as rural sanitary authority, we presume) have called for the particulars to which he refers—information which we do not possess, and which must determine the question of fee.

Dr. Edward Haughton.—We cannot interfere in the dispute.

OBSCURE PAIN IN BONES AFTER INJURY.

To the Editor of THE LANCET.

SIR,—Would some of your numerous readers kindly give me their advice under the following circumstances?

In the year 1857, whilst residing in India as a civil medical practitioner, I was temporarily attached to the 13th Native Infantry, and served with them during the siege of Lucknow. On one occasion whilst engaged attending an officer who had been mortally wounded in a sortie I was struck on the right clavicle by the fragment of a shell. The shock was pretty severe, but it passed off in a short time, and Dr. Boyd, of H.M.'s 32nd Regiment, who examined the part at once, was unable to detect either fracture or dislocation of the bone, or the slightest abrasion or discoloration of integuments. I resumed duty next day perfectly well. In the year 1877 (that is, twenty years after the occurrence) I was suddenly seized with a pain in the humeral end of the right clavicle, extending in front as far as the nipple of the breast, and in the back along the right scapula to its inferior angle; and since that time to the present I have never been entirely free from it.

Having consulted some of the most eminent men of the profession and tried every means to obtain permanent relief without success, I now, as a *dernier ressort*, place my case in the columns of THE LANCET.

I am, Sir, your obedient servant,

PATRICK BRERETON,

Retired Medical Practitioner, I.C.S.

Limerick, Aug. 11th, 1880.

P.S.—My own opinion is that the affection is of a neuralgic character; but I wish to observe that my brother, the late Major Brereton, of the Royal Bengal Lancers, was a great sufferer from gout for many years previous to his death.

DEXTRO-QUININE.

THIS drug is stated to be growing in the estimation of physicians of the United States as a remedial agent in all diseases possessing a periodic character. Dr. J. J. Chambliss, in a paper in the *Louisville Medical Herald*, descants on its merits ascertained by an experience of its satisfactory results in a number of cases where the use of the sulphate of quinine was indicated. The dextro-quinine is recommended as being a safe and efficient substitute for the more expensive compounds of Peruvian bark, whilst its administration is said to be free from the so-called quinine eruption which frequently accompanies the use of the sulphate. It is also less bitter than the latter, and there is not so much certainty of the return of paroxysm in intermittent fever after its exhibition. Moreover, Dr. Chambliss asserts the especial efficacy of the dextro-quinine in "completely eradicating from the system the *materies morbi* in cases of the malarial cachexia where the blood has become so vitiated with malaria as to manifest itself at septenary periods in paroxysms of intermittent fever."

Breadtray.—1. Bristowe or Roberts.—2. Barnes.

PATIENTS' GRATITUDE, PUBLIC AND PRIVATE.

To the Editor of THE LANCET.

SIR,—I was rather startled when at church the other day on hearing the following notice read in a most impressive way to the breathless and listening congregation:—"L. L.—desires to give thanks to Almighty God for the great benefit she has received at the — Infirmary."

Now this L. L.—is a patient of mine, and I was more than astonished to hear her pouring forth her gratitude in this gushing manner. She had always been rather niggardly with her gratitude to me; indeed, had rather been inclined to impatience and grumbling, and it was partly to avoid this that I sent her, about the beginning of the year, as an in-patient to this infirmary.

I was called in again to see her when she returned, and found that she was not by any means cured, and that she was certainly far from feeling the gratitude her public prayers led me to believe. She told me she had been required when she left the infirmary to give this public testimony, and like all, or most of the other patients, had been provided with a printed form to give to the clergyman.

Now, Mr. Editor, I am a general practitioner, a member of a hard-wrought, underpaid, and often unappreciated profession, and do not by any means object to patients expressing their gratitude in a spontaneous way. It comes so seldom in my way that it falls like strange music on my ears. But surely you would object to me, or any other gratitude-craving mortal, insisting on our patients giving a public recognition of their feelings. This style of thing opens up a splendid field for the *outing* system. Why should a public institution do this thing if I may not? Why should it vaunt its cures (so-called) like any quack, when such an easy road to fame is shut to me? It may be urged that because it is a public charity, and supported by voluntary contributions, it is well, nay, imperative, to keep its existence before the public. But surely this can be done in a way somewhat less offensive to professional taste than by publicly praying over a patient's recovery, as if such an event were a national blessing, and an event which happens so seldom in the country that all who hear of it should rejoice. Being personally concerned I may have felt it too much, but under the circumstances such a proceeding seemed to me to outrage common sense, common fair dealing, and indeed common decency. "By their fruits ye shall know them," should be the guiding canon for public no less than for private practitioners.

The general practitioner (especially in the village) is already heavily enough handicapped in the race with the "big doctor," without calling in the aid of grateful prayers in the church service. No one could or would object were this the spontaneous offering of a really grateful patient, but when a printed form of public thanksgiving is pushed into the hands of patients on leaving the infirmary it becomes ridiculous, not only in the eyes of common sense, but in the eyes of the patients themselves. Such, however, is the opinion of

August, 1880.

A VILLAGE DOCTOR.

QUERY.

To the Editor of THE LANCET.

SIR,—I read with interest the report in your issue of the 14th inst., of a case of quassia poisoning at Newark, but it occurs to me is it not possibly a case of alcoholic poisoning? for when one remembers that at least nine drachms of rectified spirit were retained in the rectum, and absorbed by a child aged four years, I think the amount is sufficient, and likely to cause all the symptoms described; and again, the recovery was as rapid as the illness was sudden.

Yours truly,
Newington Infirmary, S.E., Aug. 16th, 1880.

REG. MAPLES.

A SUGGESTION.

To the Editor of THE LANCET.

SIR,—Some correspondence has lately been current in THE LANCET concerning the atmosphere of hot-air baths. I should like to know whether it is practicable to preserve tropical plants in the sudatorium, and if so whether they might not well be employed to counterpoise, as far as may be, the effects of unscientific ventilation.

Yours obediently,

Finsbury-circus, E.C., Aug. 17th, 1880.

H.

SEATS FOR SHOPWOMEN.

WE are glad to find that our advocacy of seats for girls in shops has the effect of moving inventors to improvement in this direction. A common objection raised by some employers is "*Stools and chairs are an intolerable obstruction and nuisance behind the counter.*" This safe retreat from our arguments and appeals is likely to be demolished. Messrs. Colman and Glendenning, of Norwich, and 62, St. Martin's-le-Grand, London, have placed before us a working model of an exceedingly simple and ingenious contrivance termed the patent automaton, which effectually removes the objection. It consists of a disc or seat of wood, supported on a single stem of iron, which at its base works in a socket secured to the floor. A touch is sufficient to cause the seat to fall into a recess (the space otherwise occupied by a very small drawer is sufficient), or to assume a horizontal position for use at the distance of about a foot from the counter. Though light, and even elegant in appearance, we are assured by the makers it is of ample strength and solidity. One recommendation will certainly be the ease with which it may be fixed, and its modest price.

Mr. W. Berry (Wigan).—The paper is marked for insertion.

"HOW ANTI-VACCINATION STATISTICS ARE MADE."

To the Editor of THE LANCET.

SIR,—I notice in your impression of the 21st instant a paragraph with the above heading. As my name is mentioned, it may be well for me to write a few words on the subject.

In the first place, the report of my evidence as extracted from the *Northern Echo* is inaccurate and not sufficiently full. My assistant, I stated, had attended the child about a month previously for a syphilitic eruption, and it had improved under the specific treatment. Being absent in the south at the time, he was not called. The eruption after death, as I saw it, could have been, in my opinion, no other than syphilitic. Secondly, from the history of the case, and my seeing the family, I formed my private opinion, for which I was asked at the meeting of the Court, that it was not hereditary, and that it might have been produced by vaccination if the operation had been performed carelessly. To prove how little worth was such an opinion, I gave an example to show that the age at which a child is usually vaccinated, or soon after, is very commonly the time when a hereditary syphilitic taint shows itself. The case was this: Shortly after I had vaccinated a child (about a fortnight after), syphilitic signs began to show themselves, progressed, and the child died. *The mother and father* blamed vaccination for it. As I am always extremely careful about the lymph I use, as also about the cleanness of the lancet, I told the parents it could not have been from the vaccination that the child died. About a year after another child was born, and I proposed not to vaccinate this one until he was six months old, *in order to show that it was not from vaccination that the former child had died.* About the same age this child was taken with the same signs, same rash, same progress to fatal end. I had not to "retract," but the parents were sensible enough to give up the idea of vaccination being the cause of death in the former case. For my part I am strongly in favour of compulsory vaccination and of revaccination, and urge it at every opportunity, and therefore felt much grieved that I had to express the opinion I did in open Court. By my qualifications I made my opinion of as little worth as evidence as I felt it to be myself. As I had sworn "to give the truth, the whole truth, and nothing but the truth," I considered I was bound to give truly my opinion, and, as weakly as I felt it myself, as evidence.—Yours truly,

West Hartlepool, Aug. 23rd, 1880.

EUSTACE M. SWANWICK.

A *Constant Reader* is quite mistaken when he states that the Indian Government has declined to recognise the rank conferred by Royal Warrant on the surgeons of the A.M.D. Indeed this higher relative rank is one of the grievances of the I.M.D. With regard to his complaint that the surgeon only draws 317 rupees a month instead of 450, which he conceives ought to be the rate, he must be aware that this was clearly laid down as the rate in the paper furnished to each candidate before he entered the service. We cannot, therefore, see that there is any reasonable ground of complaint on this point.

M.R.C.S. should bring the case under the notice of the Medical Defence Association.

W. E. M.—We are not aware that any such book has been published.

GUY'S HOSPITAL.

To the Editor of THE LANCET.

SIR,—Whether the nursing in any hospital is carried on by sisters, by ladies, or by women of the same class as their patients, that "system" which does not in every way render a hearty loyal obedience to the medical staff ought to be promptly extinguished. The ladies at Guy's, whatever they may be called, are not "sisters." The ladies nursing at University College Hospital are sisters, and, on the whole, the medical staff and this sisterhood seem to jog along pretty well together. The fact is, there are sisters and sisters, and if the doctors could only pick and choose the sisters to work under them, I believe even Guy's itself might be in peace and order in a week. Anyhow, I think it a great pity that Dr. Roxburgh used such an expression as "malign influence."

I am, Sir, yours faithfully,

ARTHUR BRINCKMAN.

All Saints', Margaret-street, Aug. 15th, 1880.

A MEDICAL CORONER AND A MEDICAL WITNESS.

THE *Belfast Evening Telegraph* reports a very unseemly altercation between the medical coroner for the borough of Belfast and a medical witness, Dr. Graham. The latter gentleman complained, when served with the summons, of insufficient notice, and we think most reasonably. He went in person to say that he had an engagement within ten minutes of the time at which he appeared. The coroner alleged no urgency in the case, and did not justify the short notice. Finally, the coroner ended by ordering the constable to take Dr. Graham into custody, and so detained him till he gave his evidence! Our contemporary asks, Is this a creditable proceeding? We should reply in a monosyllable of two letters; and we regret to find it very difficult to justify the coroner.

X.—We are aware of the grievance complained of, and will do our best to remedy it; but we think the publication of our correspondent's letter would do more harm than good.

"COMBATANTS AND NON-COMBATANTS."

To the Editor of THE LANCET.

SIR,—From an article with the above heading which recently appeared in one of your medical contemporaries, taken in connexion with some remarks of yours in a late issue upon the contemplated abolition of the power of exchanging between army medical officers at home and in India, it would appear that the old dictum of each succeeding Secretary of State for War in the days of agitation—namely, "that medical officers cannot expect to be treated differently from all other officers in the service" (e.g., in the matters of forage, exchanges, sick leave, &c. &c.)—is no longer to be heard, and that the old time-honoured custom of giving with one hand and taking from us with the other is still to obtain.

Government have certainly obtained a supply of candidates as a result of the last Warrant, and their troubles for a time are consequently at an end; but it may be well to remind them that the action lately taken by the whole profession in this army medical question can be taken again, though with very much more effect, now that men of the stamp of Lyons and Farquharson are members of the House of Commons.

Medical officers care not what they are styled, but since it is now a well-known fact that they expose their lives freely on the field and in the hospital, and that their mortality is, consequently, far higher than that of any other body of officers, it is surely high time that in the matters of exchanges and of reckoning half-pay service (due to ill-health incurred in and by the service) towards voluntary retirement, they should be treated in the same manner as their purely combatant brother officers, to say nothing whatever of those other departmental officers included "as part of the staff of the army," and so entitled to the advantages connected with voluntary retirement, as laid down for combatant officers in Clauses 83a and 83b in Army Circulars of 1st March, 1880, under the heading "Royal Warrant, &c."

I am, Sir, your obedient servant,

August, 1880.

X.

PROVISION FOR THE RELIEF OF SUFFERERS IN RAILWAY ACCIDENTS.

To the Editor of THE LANCET.

SIR,—In an article on "The Liabilities of Foreign Employers," in THE LANCET of July 24th, you mention the fact that in France the railway companies "provide each train with a large medical chest, with splints, bandages, and even the necessary implements for amputations, &c." Shortly after the terrible collision at Abbots Ripton, I wrote to *The Times*, suggesting that each train should carry such a chest in the guard's van, containing splints, bandages, and the means of arresting the hæmorrhage. The need of some such provision was brought forcibly to my mind by my own experience in a railway collision shortly before, where one of the passengers was seriously injured, and the collision having occurred between two stations, in a wild country, two hours elapsed before we could get even a draught of potable water. The suggestion, however, seemed to the general public to be so absurd that the editors of some provincial (and even colonial) papers made it the subject of special, no doubt to their readers, very amusing articles.

Perhaps, Sir, when it is known that this plan is already adopted in France, and if it receives the powerful assistance of your approval, it may some time in the distant future be thought worthy of adoption even in England.

I am, Sir, yours truly,

Manchester, August, 1880.

W. H. BARLOW, M.D.

CONSULTANTS VERSUS GENERAL PRACTITIONERS.

To the Editor of THE LANCET.

SIR,—In answer to a letter from "A Country Practitioner," I quite think the treatment received by country practitioners at the present day is intolerable, and should advise the gentleman to make himself conversant with all branches of his profession as well as he can, or else I am afraid he must not expect much consideration at the hands of a great many consultants and specialists. I live a few miles from a town of 60,000 people, and I find that etiquette is a thing unknown to the profession in it, so that I have suffered in a similar way to your correspondent; but I have taken measures to show my patients that such conduct is hateful to me, and not conducive to their happiness or health.

Yours truly,

August, 1880.

RUS IN URBE.

Nemo.—Works on the subject are legion. Write to Messrs. Spon, Charing-cross, and ask for a list of works published by them relating to sewerage and drainage and utilisation of sewage. Consult Parkes' and Wilson's text-books on Hygiene (Messrs. Churchill), and Professor Corfield's work on the Treatment and Utilisation of Sewage (Macmillan and Co.)

M. H. J..—We cannot advise; consult a practitioner.

"TREATMENT OF SCARLET FEVER BY WARM BATHS."

To the Editor of THE LANCET.

SIR,—Under this heading I saw a letter in THE LANCET of Aug. 14th, by Dr. Lush, of Weymouth. It so happened that at the time he refers to I was acting as assistant to Dr. Aldridge, of Dorchester, in Dorset. We had had a few isolated cases of scarlatina of a mild form for several months, but in the month of August, 1870, an epidemic burst upon the town and neighbourhood with terrible violence. I am sorry to be obliged to confess that many died, and that I cannot with Dr. Lush say "we did not lose a single case." The warm baths were tried in the way recommended by Dr. Lush, and in many cases answered admirably, but neither the warm, the tepid, nor the cold had any effect upon the worst cases.... Though I highly approve of warm baths, as soothing to the system, and calculated to keep up the action of the skin, still in the worst forms of this fever baths are no good whatever.

I am, Sir, your obedient servant,

F. WILLIAM SMITH, M.D.

Leamington, Warwick, August 16th, 1880.

"RUNNING" IMPULSE IN EPILEPSY.

To the Editor of THE LANCET.

SIR,—Your correspondent, Dr. J. D. Miller, describes an interesting case of the "running" impulse in epilepsy.

Some time ago I had the opportunity of observing a similar case, which was unusually instructive from being discovered to have been occasioned by masturbation. Measures were taken to put a stop to this practice, and the patient recovered from the epileptic symptoms.

Yours &c.,

August 24th, 1880.

Clinical Lecture

ON THE

ESSENTIALS OF WOUND TREATMENT.¹

By SAMPSON GAMGEE, F.R.S.E.,

SURGEON TO THE QUEEN'S HOSPITAL, BIRMINGHAM.

GENTLEMEN,—Here is a pad of pure absorbent gauze and cotton, which has been removed from the left hand of a young person whom I happened to see the other day running down the street, to seek surgical aid at a neighbouring dispensary. Under a handkerchief stained with blood I found a clean-cut wound, extending an inch and a half from the dorsal aspect of the first knuckle round into the palm. A little artery spouted. The edges of the skin admitted of easy approximation, which I maintained with the elastic pad and a few compressing turns of absorbent bandage. In a few hours bloody serum had permeated the centre of the dressing, which was left to dry by evaporation. When, at the end of five days, I took off the bandage and pad, the fine linear cicatrix was barely visible, and the surrounding skin dry and painless.

I was in the hospital on April 29th when the man now before you was brought in. A cloth soaked with blood surrounded the left hand and forearm, and we were told that the accident had happened a few minutes previously, while the man was grinding a matchet,² on a millstone weighing a ton, and revolving rapidly by steam-power. The steel blade flew into several pieces, one of which appeared at a first glance to have nearly cut off the hand. The gaping wound extended for two and a half inches across the front of the wrist. The superficial tendons were divided, and the ulnar artery bled freely. I passed an acupressure needle under the proximal end of the divided vessel, and after satisfying

FIG. 1.

myself that the wound was free from a foreign body, brought the edges accurately together by five points of silver suture. The hand and forearm were surrounded with absorbent gauze and cotton pads and compressing bandage, the elbow bent at an acute angle, the palm of the hand rested on the upper end of the sternum, and perfect rest secured, by circular bandage round the trunk and the recumbent position. The acupressure needle was taken out on the fourth, the

stitches on the fifth day, when the wound was nearly healed. On the eighth day the man was made an out-patient, and the same dressing was renewed every fourth day. This is the fortieth day since the accident, and you observe how fine and firm the scar is, without any subcutaneous matting, and with perfect freedom of the joint in every direction.

From first to last, neither of the two cases I have just brought before you was touched with a drop of liquid; the healing process advanced steadily and without complication under dry absorbent dressing, elastic pressure, perfect rest and position.

I satisfied myself with looking on while the next case was treated on the same principles by our house-surgeon, Mr. J. W. Moore. Just before admission E. H. had fallen forward on the edge of a barrel, which inflicted a wound nearly three inches long a little to the left of the chin, exposing a considerable portion of the lower jaw and its depressor muscles. The edges of the wound were at once accurately adjusted with five points of silver suture, a fine drainage-tube was secured in the lower angle, and smooth pressure exerted with a fine soft bandage over a pad of pure absorbent gauze and cotton. The first dressing, with two sutures and the drainage tube, was removed the third day, when the absorbent pad was found to have taken up some sanguineous discharge, and the greater part of the wound was healed. The three remaining sutures were removed on

FIG. 2.

the eighth day. On the tenth day the wound was solid as it is now; the cicatrix linear, with the exception of the lower angle, which presents a slight pucker at the point where the drainage-tube was introduced. The dry absorbent and compressing dressing was changed four times altogether.

The essential features in the treatment of the three cases just briefly noticed were—firstly, accurate adjustment; secondly, absolute rest; thirdly, perfect drainage. The means for attaining these ends vary, but if you keep them steadily in view, and are light-handed and not meddlesome, you will not have much trouble in the treatment of the vast majority of incised wounds.

Here is a dressing (Fig. 3) I removed a few hours ago from the crown of the head of a private patient on whom I had operated three days previously for the removal of a sebaceous tumour. As soon as I had turned it out I adapted the edges accurately, and exerted pressure for a few minutes with the finger over a pledget of dry absorbent cotton; when this was stained with blood, I substituted for it a similar pledget soaked in styptic colloid, and over it a strip of dry lint. Under pressure for about three minutes longer the dressing dried and the patient left my consulting-room. When I saw him the next day, he was perfectly comfortable and attending to his business. It was not until the expiration of the third day that I poured a little ether over the pad to soften it; this was the work of a few seconds. On removing the dressing, the clean and dry scalp presented a firm cicatrix, of which you see, and feel, a linear cast in the centre of the dressing. The balsamum traumaticum of the old surgeons, the compound

¹ The materials of this lecture, condensed, re-arranged, and illustrated for the convenience of the readers of THE LANCET, formed the subject of four mornings' instruction to my clinical class, during the past session.

² A kind of slightly bent broadsword, used in the West Indian plantations for cutting down sugar-canes.

tincture of benzoine, collodion, and allied substances, are useful in wound treatment, on the same principle as Dr. B. W. Richardson's styptic collod. This substance is produced by saturating ether with tannin and gun-cotton, a

FIG. 3.³

little tincture of benzoin being added.⁴ It has the advantage of drying very rapidly and acting at the same time as a styptic and a splint, checking effusion and preventing motion.

A more formidable wound than any of the preceding, but treated on substantially the same principles and with equal success, was that of the patient now before you with this extensive cicatrix on the right side of his head. T. W.— was admitted into the hospital on April 29th, after being struck on the head by the beam of a steam-engine in motion. The wound commenced just behind and above the right ear, and extended upwards and backwards for a distance of three

FIG. 4.

and three-quarter inches, then forwards at right angles for four inches. The triangular flap was turned down and the bone exposed corresponding to its whole extent. Hæmorrhage profuse. The flap was replaced and secured with four silver sutures, a large dry pad of absorbent gauze and cotton, and a smoothly compressing bandage. Three days afterwards, the temperature being 102°4', the dressings were removed. The pad was soaked with a considerable amount of red serous discharge, but there was no redness of the skin, and the flap looked healthy and in good position; two sutures removed and fresh dry gauze and cotton pads applied, with

⁴ Sampson Gamgee on the Treatment of Wounds. London: Churchill. pp. 31 et seq.

increased pressure. The temperature fell steadily and was normal at the third dressing on the seventh day after admission. There was altogether very little suppuration, and the man left the hospital (May 19th) at the end of three weeks, the dry absorbent pads having been changed six times, and the cicatrix being sound throughout.

No cases illustrate more forcibly than extensive scalp wounds the advantages of immediate, perfect, and immovable adjustment, dry and infrequent dressing, surface-drainage, and elastic pressure.

We have so far been engaged in considering the treatment of recent simple wounds. Here is a much more serious one. My attendance was requested on the 11th by Mr. P.—, who has kindly attended this morning for the class inspection. A fortnight previously a heavy piece of timber had inflicted a deep oblique wound in front of the right forearm just above the wrist. It was dressed with carbolic lotion, and, when inflammation supervened, with poultices. I found the man suffering intensely, the hand and forearm red and greatly swollen, wound measuring four inches by three-quarters of an inch, the bottom dirty grey, and the edges everted. I wiped the limb dry with a pledget of absorbent cotton, raised the hand vertically above the head, and surrounded it and the forearm as far as the elbow with dry pads of pure absorbent gauze and cotton. A softened millboard splint was placed on the dorsal, another on the palmar aspect of the limb, and a soft bandage applied with even pressure. The hand was now lowered and fixed on the chest, the tips of the fingers touching the opposite shoulder. A bandage round the trunk maintained immobility. The patient was at once easy, slept well the same night, and has not had a single bad symptom. He is engaged in an important patent manufacture, and has not lost an hour since I first saw him. The apparatus soon became loose from subsidence of the swelling; fresh cotton pads were applied with increasing pressure, and at the end of a week the wound was clean and half its former size, the surrounding skin pale, dry, and shrunken. In the course of a few days the healing advanced more slowly, and I dressed the wound with a lotion containing two grains of sulphate of zinc, a drachm of glycerine, and twenty drops of compound tincture of lavender, to the ounce of water, continuing the elastic pads and increased pressure. The stimulating effect was very apparent; the blue line of new skin advanced rapidly from the edge. I then omitted the lotion, and in another week the cicatrix was solid under a dry compressing pad. The cicatrix is now solid, and every movement perfect.

My first object was to empty the limb as much as possible of redundant blood; this I did by raising it vertically and compressing it under elastic pads of absorbent gauze and cotton and pasteboard splints. The latter are made with thin, rough millboard, which in the dry state tears easily to any shape, and absorbs water rapidly. According to the strength required, I put two or three thicknesses together, with intervening strips of bandage brushed over with thick mucilage. The material moulds beautifully under pressure, and acquires the strength of papier maché. When the swollen limb shrinks, accurate fitting being of the essence of success for pressure, the splints so constructed can be readily softened by pouring over them a small quantity of hot water; reapplied under pressure they mould and solidify again and again. The pads of absorbent gauze and cotton are beautifully elastic, a quality which is of the utmost value for safe, efficient, and comfortable pressure, which, with position, is the great agency for regulating the vital dynamics of the circulation, preventing effusion, and promoting absorption and healthy consolidation. For those who prefer the pads medicated with boracic, benzoic, or carbolic acid, Messrs. Southall Brothers and Barclay specially prepare them, but as a rule I only use the pure gauze and cotton pads, which may also be obtained from that firm. If, as sometimes is the case, a wound requires stimulation, I apply an appropriate lotion as in the preceding case. When the neighbourhood of a sore is very irritable, glycerine, pure or diluted with water, is an excellent application, as was long since demonstrated by Demarquay in a monograph of the highest clinical interest.⁵

The advantages derivable from an adaptation of therapeutic resources to the requirements of particular cases

⁵ De la Glycérine et ses Applications à la Chirurgie et à la Médecine. Par M. Demarquay. Troisième édition. Paris: Asselin. 1867.

are well illustrated by the next two patients to be brought under your notice.

I abstract notes taken by Mr. Aubrey Finch, while acting house-surgeon, of the history of T. H—, aged thirty-three, who presented himself in the out-patient room on the 17th of May. The patient is a well-built, healthy man, by occupation a wood-turner, standing all day at his work. Seven years ago a piece of lignum vitæ grazed his right leg, and produced inflammation and ulcers, which have never since entirely healed, though treated by a variety of surgeons. When I first saw the leg (May 17th) it was covered with varicose veins; the skin, especially in the middle third, was thickened, purple, shining, and very tense and tender. On the inner side was a sore three inches in length, one inch and a half wide, with dirty greyish-yellow surface, and a few weak-looking, flabby granulations; edges uneven. The measurements round the two calves, six inches below the patellæ, were—right, 14½ inches; left, 12¾ inches. Placing the man on his back on a couch, and raising the right leg vertically, the leg almost immediately became pale, the veins empty, and the tissues of the calf, previously so tense, flabby. At the expiration of sixty seconds from the time that an assistant held the right foot vertically above the pelvis, I measured the right calf at the exact spot previously measured. The decrease proved to be exactly one inch in one minute. A piece of lint soaked in glycerine was placed over the sore, the limb was covered with dry pads of pure absorbent gauze and cotton, bandaged with light pressure, and swung. The patient was at once easy, and two days afterwards the limb was pale and shrunken, the sore clean, healing, and much diminished in size. The same treatment was continued, and the note on the eighth day is to the effect that the sore had nearly healed, and the calf measured, at the point previously tested, 12¾ inches—a decrease of 1½ inch. On the twentieth day from the commencement of our treatment the large sore which had proved rebellious for seven years was firmly healed, and the surrounding structures were pale, supple, and painless. Rest, position, and pressure have doubtless been the great factors in this healing process, the glycerine acting as a soothing application to the sore and skin, which we found so exquisitely tender. The cotton pads absorbed whatever discharge was poured out, but their elasticity as a medium of smooth pressure was their chief value. Those of you who watched this and the other cases closely noticed the scantiness of the discharge. One effect of perfect rest, elevation, and pressure is to lessen the afflux of blood to a limb so considerably that there is only enough for nourishment—none, or scarcely any, for effusive and cell proliferation; so shrinkage, dryness, sweetness, and reparative consolidation proceed abreast.

These truths receive further corroboration from the case of severely contused and open knee-joint in Ward 3. The patient, E. L—, aged 15, was brought on the 21st of May last, with a wound two inches long just on the outer side of the left patella, which was exposed, as were also the external lateral ligament, the outer condyle of the femur, and the corresponding tuberosity of the tibia. There was free escape of synovia and blood. The wound was inflicted by the cog-wheel of a steam-printing machine in motion, over which the lad was kneeling. While Dr. Oliver administered chloroform, Mr. E. M. Osborn, the acting house-surgeon who admitted the patient, brought the edges of the wound together with three points of silver suture, covered the knee with dry pads of pure absorbent gauze and cotton, and with a compressing bandage immobilised the limb in the straight position by the aid of pasteboard splints. When I saw the case a few hours afterwards, the patient was so tranquil, and the apparatus in such good position, that I made no other alteration than to raise the lower end of the bed six inches, and place under the injured leg one of my sand-and-water pillows, to ensure more perfect ease and immobility. The copious notes record the happy progress of the formidable injury. The wound into the knee-joint closed thoroughly by the first intention, although a purely superficial sore resulted from the sloughing of the contused skin. The temperature has been high on several occasions, but there has never been the slightest redness of the skin or puffiness of the joint. The patella has been throughout well defined and movable. On an average the compressing cotton pads have been changed every five days, and there is no reason to doubt that the limb will in a short time regain all its former mobility and strength. I have never seen so

formidable an injury recover with less complication, and if you will study the case in conjunction with the others which I have brought under your notice, you will be assisted in forming a just estimate of the essentials in wound treatment. They are—accurate coaptation and absolute rest, to which position and pressure are eminently conducive. As a rule, dressing should be dry and infrequent, and drainage adapted to circumstances. No amount of clinical experience can dispense with the necessity of closely watching the thermometer; and while attending to the constitutional state, the local process of healing, when languid, may be accelerated by some of the well-known stimulating and cleansing local applications. When the parts are irritable soothing applications are of service, and of these the least harmful and most generally useful is glycerine.

In directing attention to a group of cases successfully treated on demonstrably sound principles of physiology and surgery, I have expressly avoided entering upon a controversy which has for some time divided the surgical world. Disputations may be more interesting than profitable; they often do much towards unveiling the truth, but they not unfrequently obscure it.

The adage that many roads lead to Rome finds abundant illustration in surgical practice. Pin your faith to no master; be a slave to no system. The scheme of nature is broad and comprehensive; truth is catholic and many-sided. Your chances of interpreting it rightly and practising it safely will be enhanced, in proportion as you keep your mind unbiased by theories and fashions, and strive to imitate nature in method and in means.

Lectures

ON THE

PHYSICAL EXAMINATION OF THE MOUTH AND THROAT.

Delivered to the Junior Class of Clinical Medicine, University College,

By G. V. POORE, M.D., F.R.C.P.,

PROFESSOR OF MEDICAL JURISPRUDENCE, UNIVERSITY COLLEGE; LATE ASSISTANT PROFESSOR OF CLINICAL MEDICINE; ASSISTANT PHYSICIAN, AND PHYSICIAN IN CHARGE OF THE THROAT DEPARTMENT OF THE HOSPITAL, ETC.

LECTURE VI.

STERTOR; HICCOUGH; THE EXAMINATION OF THE OUTSIDE OF THE NECK AND NASO-PHARYNX; DYSPHAGIA.

GENTLEMEN,—There are certain other pseudo-vocal sounds of which a few words may be said as to their value as signs of disease.

The first of these is *stertor*. *Stertor* is of two kinds—palatal and laryngeal; their import being very different. Palatal *stertor*, or snoring, is caused by a vibration of the soft palate, brought about by the in-rushing streams of air through the mouth and nose. It is most easily produced when air is admitted both behind and in front of the soft palate, and is often audible in those who sleep with their mouth open. The deeper the sleep, the more easily is snoring produced, owing probably to the complete relaxation of the palatal muscles. It is heard at its maximum in cases of apoplexy, cerebral concussion, and poisoning with alcohol or opium. It can be produced at will, and it seems to me most easily produced when the air is inspired with extra force in order to overcome some slight obstruction at a point above the soft palate. When we wish to imitate it, we partially open the mouth, put the compressor naris into action, and inspire deeply. When the mouth and nose are both wide open *stertor* is not so easily produced. With the nose completely closed it is possible to produce only a very imperfect *stertor*. With the mouth completely closed no *stertor* is produced even during very deep inspiration. In children and adults who have big tonsils excessive snoring is very common, owing to the increased force of the blast

of air which has to be drawn through the narrowed faucial aperture. It is worth considering how much extra work is thus imposed upon a child with big tonsils. The causes of palatal stertor are—(1) extreme relaxation of the palate; (2) increased force of inspiration.

Laryngeal stertor is not to be confounded with palatal stertor. It is a non-vibratile stridulous sound, and betokens some obstruction to the passage of air through the larynx. When this laryngeal stertor is permanent it is usually spoken of as stridor. When the larynx is irritated, as by the passage of a brush on to the vocal cords, the glottis is partially closed and the inspiration becomes stridulous. Of course, if the closure of the glottis were perfect no stridor would be produced, because the vocal cords could not be made to vibrate by the in-going blast. Stridor is produced by forcible inspiration through a partially closed glottis. It is an *inspiratory* sound, be it observed, and not an *expiratory* one. In cases of paralysis of the posterior crico-arytenoid muscles the glottis is only partially opened during inspiration; and if the inspiratory effort be at all quickened, the semi-approximated cords are made to vibrate, and stridor is produced. During expiration the cords are thrust asunder by the out-coming blast, and no stridor occurs. The presence of inspiratory stridor, combined with unimpeded expiration and good vocalising power, would be sufficient ground for the diagnosis of paralysis, or want of power in the posterior crico-arytenoid muscles.

I wish to draw your attention to the fact that, in the stridor which occurs in this condition, there is no question whatever of any spasmodic action. It is entirely a paralytic or paretic phenomenon. Now we have the same kind of stridor (1) in chloroform narcosis, when it is a sign of imminent danger; (2) in whooping-cough; (3) in laryngismus stridulus. In all these conditions it has been ascribed to spasm, but, as I think, without sufficient cause.

In *chloroform narcosis*, at a time when every other muscle in the body is in a state of complete relaxation, it does not seem reasonable to expect a laryngeal *spasm*; for, be it observed, this stridor only occurs when narcosis is far advanced, and all spasmodic muscular action (which is common enough in the early stages) has passed away. Again, the stridor is removed by a forcible traction on the tongue, which by reflex stimulation brings about a contraction of the posterior crico-arytenoid muscles. Lastly, there is no stridor during expiration, which there should be if the cords were *spasmodically* held in apposition. We have seen that stridor undoubtedly does occur as a purely paralytic phenomenon, and I believe that that which accompanies chloroform narcosis is paralytic also.

In *whooping-cough* the stridor is produced after a prolonged and violent expiratory effort, when the diaphragm descends with force, and air is drawn violently through the glottis. Now as long as the proper relation exists between the size of the glottic aperture and the rate of movement of the incoming air the respiration is noiseless, but if the chink be not opened wide enough, and the incoming blast be violent, then stridor is produced. Probably, or rather certainly, both these conditions exist in whooping-cough, and the assumption of a glottic *spasm* is beyond the power of proof. In whooping-cough vomiting is a prominent feature, and one can conceive that a catarrhal condition involving the larynx and anterior and upper part of the œsophagus might well interfere with the proper action of the posterior crico-arytenoid muscles which are close to the summit of the œsophagus.

The remarks which I have made concerning whooping-cough apply also to *laryngismus stridulus*—that sudden arrest of respiration, followed by a crowing inspiration, which is so liable to occur in sickly children, especially the rickety. We know that in rickety children the bones and cartilages are soft, and the muscles flabby and weak. We know also, from an experiment of Marshall Hall's, that if a syringe be tied into the lower end of the trachea of a dead animal, and a very rapid exhaustive movement of the piston be made, the soft parts around the larynx will fall together and prevent the ingress of air to the larynx. In the flabby-tissued rickety child it is highly probable that something of this kind occurs; the aryteno-epiglottic folds probably fall together, and the posterior crico-arytenoids very likely fail to act, and hence the difficulty of getting air into the larynx. It has been assumed that laryngismus stridulus is a true spasm because it is accompanied by the so-called carpo-pedal contractions of the fingers and toes, and spasm in one place has led physicians to infer a spasm in

another. These carpo-pedal contractions are probably brought about by the condition of asphyxia induced by the closure of the glottis. Convulsive action very commonly attends carbonic-acid poisoning, especially in children.

Hiccough is a symptom of disease concerning which a few words may be said. It is caused by a sudden spasmodic descent of the diaphragm at a time when the glottis is imperfectly opened, and hence a catching noise is produced by the passage of the air over the vocal cords. The essential part of the trouble is the descent of the diaphragm, which occurs suddenly and irrespective of any respiratory need. Normally, as the diaphragm descends in inspiration, the posterior crico-arytenoid muscles simultaneously contract and the vocal cords separate; but when the diaphragm descends suddenly and irrespective of any respiratory need, the vocal cords do not separate, and hence the noise of hiccough is produced. The cause of hiccough is usually to be found in an over-distended stomach, and it is very common in children in whom convulsive movements are very easily produced. Any irritation of the phrenic nerve on the under surface of the diaphragm, such as peritonitis, will cause hiccough. Irritation of the trunk of the phrenic will produce it also, and occasionally it is of cerebral origin.

Stridor may be inspiratory, expiratory, or both. One cause of inspiratory stridor is a failure of the glottis to dilate. It may be produced also by warty growths, which are drawn towards the glottis only in inspiration. A pure expiratory stridor may be caused by a growth below the cords being blown upwards into the glottic chink during expiration. A stridor accompanying both sounds is indicative of a narrowing of the glottis of a permanent character. It is very important to listen accurately to the time of any laryngeal noise.

There is one common symptom of throat disease concerning which it may be well to say a few words. This is *dysphagia*, or difficulty of swallowing. Dysphagia may arise from paralysis or spasm of the pharyngeal muscles, from pain, or from mechanical obstruction. Each of these four causes is produced by many different conditions, some of which I will enumerate.

Paralytic dysphagia is most common as a sequela of diphtheria, owing to paralysis of the soft palate and the superior constrictor of the pharynx. It occurs also in bulbar paralysis, and when, as generally is the case, sensation as well as motion is in abeyance, food is very liable to find its way into the larynx, to the imminent risk of the patient's life. Not unfrequently also food returns through the nose.

Spasmodic dysphagia occurs in its most marked forms in hydrophobia, and occasionally in spinal meningitis. It is said to occur also in belladonna poisoning, but whether this be due to spasm or to excessive dryness of the mucous membrane is not quite clear. Any source of irritation of the throat, such as a fish-bone, or possibly a small ulcer, may cause a spasmodic contraction of the pharynx. Occasional trifling spasm is not an uncommon occurrence with patients who suffer from irritative dyspepsia. The sensation of a "ball rising in the throat"—the so-called *globus hystericus* which is so common in hysterical subjects—is probably due to a spasm of the œsophagus and pharynx. Globus, you will observe, very rarely occurs with a clean tongue, and the subjects of it not unfrequently bear evidence of subacute gastritis. It is, I believe, very often a reflex phenomenon, caused by gastric irritation, reacting upon a highly nervous, hysterical constitution, and if you want to cure it you must always attend to the state of the digestive organs. A similar spasmodic condition is brought about during emotional states, and causes the well-known sensation of "choking." There is apparently some evidence for admitting that spasmodic contraction of the œsophagus is one of the causes of "stricture" of that organ.

Dysphagia arising from pain is met with very often. It occurs during all acute inflammatory conditions of the fauces, tonsils, and pharynx. Chronic ulcerations of these parts may also bring about a like result. When inflammation and ulceration attacks the posterior part of the larynx, especially when there is great "pyriform swelling" of the posterior part of the aryteno-epiglottic folds, accompanied by ulceration, as very frequently is the case in tubercular laryngitis or laryngeal phthisis, great pain in swallowing, and consequent dysphagia, is very common. Pain in swallowing, accompanied by hoarseness, should always make one suspect laryngeal phthisis, although a certain diagnosis is not to be made without the use of the laryngoscope and a careful

examination of the lungs. An enlarged and ulcerated epiglottis, no matter from what cause—tubercular, syphilitic, or cancerous,—often produces great pain in swallowing.

Dysphagia from mechanical obstruction in the throat is common, and amongst the causes of this condition I may enumerate—1. Inflammatory swelling of the fauces, tonsils, or pharynx. 2. Organic stricture due to cicatricial contraction following upon ulcerations produced by corrosive substances or syphilis. 3. Neoplasms of the œsophagus or pharynx, whether malignant or benign. 4. Abscesses encroaching upon and narrowing the calibre of the œsophagus. 5. Tumours of the neck, of any kind, pressing upon the œsophagus. 6. Tumours of the mediastinum pressing upon the œsophagus, including aneurisms of the aorta. 7. Among other causes are pericarditis, accompanied by great effusion, exostoses from the vertebrae, fracture of the hyoid bone, and carcinoma of the lungs or pleura.

It now remains to say a few words of the physical signs of the outside of the throat, from the angle and ramus of the jaw to the clavicular arch.

Enlargement of the lymphatic glands is one of the most common signs of disease here. Enlargement of these glands is brought about by any irritation of the region whence the lymphatics come which run into them; and sometimes, when no local cause for their enlargement is detectable, it is ascribed to a scrofulous habit. I would warn you, however, that even in scrofulous subjects there is generally to be found some cause for the enlargement of any special set of glands.

When the glands at the back of the head, behind the ears, and in the occipital region are enlarged, it often indicates some irritation of the hairy scalp, as from eczema or pediculi, and no practical man finding enlarged glands in the regions indicated would fail to suspect pediculi. The glands here are often hard and shotty in the early stages of syphilitic disease. The glands at the angle of the jaw may be enlarged from inflammatory or other trouble in the pharynx, tonsils, nasal cavity, tongue, ear, and mastoid cells. Enlarged glands beneath the jaw are often caused by decayed teeth. Irritative conditions of the larynx itself cause enlargement of the bronchial glands. In mumps the parotid glands are swollen, and cause globular swellings on either side of the face. The "*socia parotidis*"—the little piece of the gland which projects forward over the ramus of the jaw—is enlarged, and this fact is often of value in arriving at a diagnosis. Occasionally we see the thyroid cartilage of the larynx too prominent. This may be, and generally is, due to the large size of the cartilage. It is well to remember that the larynx may be thrust forward by growths behind it. We have had two cases lately in the Throat Department of epithelioma of the œsophagus, in which the great prominence of the larynx was a notable feature. The thyroid body is often enormously enlarged, giving rise to what is known as bronchocele or goitre. One or both lobes of the thyroid may be affected, and the size of the tumour varies enormously. These tumours—the different varieties of which it is not necessary to discuss at present—may compress the larynx and cause dyspnoea, or they may involve the recurrent laryngeal nerves and cause laryngeal paralysis. Besides their anatomical situation, the main point in their diagnosis is the fact that they follow the movements of the larynx during swallowing. This is not the place to speak of the various tumours of the neck—simple, malignant, aneurismal, &c. That is best left to my surgical colleagues.

Palpation of the laryngeal region is often of use. The larynx may appear too fixed, and the parts to the side and behind it may appear too solid and massive. This is very often the case in malignant disease of the œsophagus. In tuberculous disease of the larynx we may find distinct tenderness on pressure over the superior cornua of the thyroid cartilage. In cases of laryngeal tumour we may occasionally feel a distinct vibratile thrill during inspiration or expiration, or both, by palpation of the thyroid cartilage. Percussion of the larynx and trachea is not of much practical value, although capable of informing us of the presence of solid matter in the larynx, or of the occlusion of its orifice. It is instructive to percuss the larynx with the nose and mouth wide open, and to hear the clear resonant note given out under these circumstances. Then close first the mouth and then the nose, and hear how the percussion note gradually becomes dull and toneless as the superior openings become completely occluded. A similar failure in tone takes place when occlusion is due to pathologic causes.

The examination of the *naso-pharyngeal cavity* can be made partly by means of direct observation through the anterior nares, and partly by employing a reflector and mirror to illuminate that part of the pharynx which extends behind the soft palate upwards to the base of the skull, and into which the posterior nares open. The ordinary reflector is very useful in inspecting the anterior nares, and in order to get a good view, the nares may be dilated by gently pressing upon the tip of the nose with the forefinger, or by inserting the common nasal speculum, or, better still, the bivalve fenestrated speculum introduced by Fraenkel. If the short hairs which grow within the margin of the nostril are found to obstruct the view, they may be removed with a pair of scissors, or smoothed down by the application of a little ordinary soap. (One may here remark that in performing laryngoscopy on persons with heavy moustachios, it is often a great help to plaster down the hair by means of a little soap, and thus make it conform to the line of the lips.) The amount which can be seen in this way varies in different individuals, according to the amount of swelling of the parts and their natural configuration. Occasionally one can see the pharyngeal wall through the anterior nares.

The inspection of the posterior nares and adjacent parts by means of the laryngoscope mirror is by no means so easy as the inspection of the larynx. The great obstacle to a good view of these parts is the soft palate, which is very apt to contract, and by impinging against the pharyngeal wall effectually prevent the inspection of the parts above it. The position of the patient, of the light and the reflector, are the same as for laryngoscopy. The tongue must be depressed on the floor of the mouth by means of a rectangular spatula, which may be held either by the patient or the observer, the former being preferable, and in many cases necessary, as the observer often needs both his hands. The mirror, which should form a very obtuse angle with its handle, must be gently passed (the reflecting surface being, of course, turned upwards) to the back of the mouth, care being taken not to touch the pharyngeal wall or the uvula. It is often a good plan to pass the mirror to one side of the uvula in order to avoid it. In very favourable cases we shall be thus enabled to see, by moving the mirror first to one side and then to the other side of the uvula and varying its degree of obliquity, the whole of the upper pharyngeal cavity and the posterior nares. The parts which we can actually distinguish are (1) the septum narium, (2) the middle and lower turbinated bones in part, (3) the pharyngeal orifice of the Eustachian tube, and (4) the mucous membrane of the upper part of the pharyngeal cavity, rendered uneven by the adenoid tissue beneath it. These parts can only be seen piecemeal, and a great deal of skill and practice is necessary in order to recognise them. The greatest difficulty is generally experienced with the soft palate. The sucking of ice and the administration of potassium bromide may do much to diminish its irritability, and by practice the patient may acquire the habit of allowing his soft palate to be manipulated. Some help may be obtained by making the patient utter a nasal sound during the whole examination, so that the palate is kept free from the pharynx, and if this fails the palate may be drawn forward by means of a thin silvered spatula passed behind it, or a loop of thread passed round the uvula. Palpation is of great use in examining these parts. A probe passed through the anterior nares will often serve to detect pieces of necrosed and carious bone, and a probe or the forefinger passed through the mouth behind the soft palate will often give very valuable information as to the swelling and consistency of the parts examined. One finger may be passed through the mouth into the fauces, while a finger of the other hand is applied externally in the neighbourhood of the angle of the jaw. In this way a very good idea is obtained of any inflammatory exudation or thickening which may exist in the pharyngeal wall or the fauces.

The nasal passage may become occluded from various causes, and when this is the case the following symptoms are presented to us as detailed by Fraenkel:—1. The mouth is kept habitually open for breathing purposes both during the day and the night. The tongue gets dry from exposure, and the patient has a vacant silly look; the breath, owing to one channel being stopped, is drawn in with great violence. It is stated that children are liable to spasmodic asthmatic attacks, due, it is supposed, to the contact of air with the lungs which has not been warmed by passing through the nasal cavity; and it may here be mentioned

that adults who have nasal polypi have occasionally suffered from asthma, but whether this is due to obstruction or to some reflex irritation is doubtful. 2. When the occlusion of the nose occurs in infants, they are unable to suck for more than a few moments at a time, owing to the constant necessity of opening the mouth. 3. The sense of smell is abolished or blunted, owing to the impossibility of effective sniffing. 4. Expiration through the nostrils is impossible, and the flame of a candle cannot be blown out when the mouth is shut, neither can the nose be "blown" so as to expel accumulated mucus, &c. By holding a candle to the nose, and asking the patient to expire through the nose, we can tell which nostril is occluded when only one is thus affected. 5. The voice is altered; all nasal resonance is abolished; the tone is muffled. This mode of speech is often erroneously spoken of as "speaking through the nose."

The chief morbid conditions which may be seen by inspection of the naso-pharynx, and which may, among other symptoms, give rise to occlusion of one or both nostrils, are: 1. Catarrhal swelling of the mucous membrane, as is so commonly seen in an ordinary cold. This catarrhal swelling, it must be remembered, occurs also in epidemic influenza, measles, and some other conditions. The secretion of the mucous membrane in this condition, varying as it does from a clear, almost limpid fluid to a thick, tenacious mucus, is too well known to need description. Occasionally the nose becomes the seat of a true purulent inflammation. 2. In scrofulous and syphilitic subjects nasal catarrhs are apt to become chronic; the mucous membrane generally becomes thickened and hypertrophied, or atrophied and shiny, and the secretion is apt to form crusts which stink and give rise to the name of *ozæna*, by which this condition is often known. 3. Abscesses of the mucous membrane occur occasionally independently of disease of the bones of the nasal cavity. 4. Syphilis very commonly attacks the nose. The presence of mucous tubercles gives rise to the "snuffles," so commonly met with in syphilitic children. Syphilitic ulcerations and infiltrations are met with here as well as elsewhere, and these conditions often lead to destruction of the cartilages, caries and necrosis of the bones, and the consequent establishment of communications between the two nostrils, or between the cavities of the nose and mouth. 5. Among the rarer causes of nasal inflammation we may mention diphtheria, erysipelas, scarlet fever, and glanders. 6. Mucous polypi may grow from any part of the nasal cavity, and vary, as you know, very greatly in size. They are usually diagnosed without difficulty, although it is well to bear in mind that other varieties of tumours, such as carcinomata and sarcomata, are found in the neighbourhood. It is well to remind you also that a hernia cerebri projecting into the nasal cavity through a congenital fissure in the base of the skull has been mistaken for a polypus. 7. It is only necessary to mention the fact that foreign bodies, such as peas and lumbrici, are occasionally found in the nose.

A very common symptom of disease of the naso-pharynx is impairment of hearing, owing to the mechanical occlusion of the Eustachian tubes. When a patient complains of being deaf, you should always examine the pharynx.

INSANITY; ITS TREATMENT AND PREVENTION.

The Presidential Address for 1880 of the Border Branch of the British Medical Association.

By J. A. CAMPBELL, M.D., F.R.S. EDIN.,
MEDICAL SUPERINTENDENT, GARLANDS ASYLUM, CARLISLE.

(Concluded from p. 339.)

In talking over the matter of the causation of insanity with members of the profession in asylum practice, I have always strongly expressed my disbelief in purely mental causes having an influence to the extent generally supposed in producing this disease, and I have been frequently answered that my views arose from my principally dealing with cases in the less educated grades of society, and that among the educated and in the higher ranks purely mental causes were far more common. I still, however, adhere to my views, and think that cases are frequently supposed to be caused by extra study, mental anxiety, overwork, religious doubts,

when, in reality, other agencies, habits, and vices have been the real cause of all the mischief.

I have already placed before you the difficulties one experiences in arriving with anything like absolute certainty at the cause of disease. In several cases of clergymen, clerks, travellers, &c., I have, on careful examination, found that where all at first pointed to a mental causation, fuller inquiry showed a physical. I am quite aware that a few general remarks or isolated cases go for nothing in dealing with such a subject. I therefore submit the following.

I have most carefully examined into the causation of the cases sent to Garlands Asylum during the past two years. In this period 238 patients were admitted: in 153 the malady was distinctly due to physical causes; in 36 only to moral causes. I have already pointed out that exception might be taken to results arrived at in an asylum whose population is principally derived from an agricultural, or at any rate a manual, self-supporting source. Let us, then, look for a moment at a likely cause of insanity—mental shock or worry from money losses. One would imagine that few things could have a more deleterious effect on the human mind than losses which keep one tottering on the brink, or that cause distinct and total ruin at once. Thrilling tales are founded on such occurrences, and our profession occasionally record wonderful cases, the result of unexpected and sudden ruin or reverses in fortune, cases of death from shock, insanity, paralysis, sudden ageing, change in colour of hair, &c. Now one of the greatest commercial casualties which of late years has affected Scotland occurred by the stoppage of the City of Glasgow Bank on the 2nd of October, 1878. This failure caused very great distress to many, ruin to some, and most undoubtedly anxiety of a severe nature to all concerned with it directly, and to many others indirectly. From the report of the liquidators,¹ I find that there were 1093 shareholders in their own rights, 100 life renters, 192 bodies of trustees, 108 persons whose wives held stock, 34 shareholders as trustees; the total number of separate persons entered on the list was 1819; 599 surrendered their estates, unable to pay the first call made upon them; 354 who met the first call were unable to pay the second. I made an inquiry from the medical officers of seven royal asylums, two private, ten district, and two parochial, to find out how many patients up to the time of my inquiry (April, 1880) had been sent to asylums from this cause. I found that six patients were admitted in whom the disease was considered to be directly caused by this bank failure, while in two it was considered the indirect cause. In Garlands, in 1879, seventeen cases were sent in from excessive drinking, and these from two counties in one year. I do not for one moment doubt that many cases have been evilly acted upon by this failure; probably cases of insanity have occurred which did not require asylum treatment. I am only dealing with this failure as a factor in causing insanity, which required asylum treatment; and the result of my inquiry shows that a bank failure of a magnitude which allows one to call it a national calamity, which directly affected 1819 persons—and who knows how many indirectly?—which must have produced an appalling amount of mental shock, an immeasurable amount of anxiety and worry, and as yet unknown amount of hardship, only sent eight persons to the twenty-one principal Scotch asylums. This should lighten the minds of directors.

During 1876 and 1878 the Commissioners in Lunacy, with the co-operation of the medical officers of asylums, collected and tabulated certain data, among others the causes of the insanity (arrived at after careful scrutiny and consideration of each case individually on the part of the asylum medical officers), with regard to the admissions which took place into English asylums. I consider that the return for 1878 is the most accurate of the sort that we have ever had access to, and I therefore refer to it. 13,309 were admitted into English asylums during 1878. Moral causes as the excitant or predisposer were considered to have caused insanity in 3199 cases; domestic trouble, adverse circumstances, mental anxiety, overwork, religious excitement, love affairs, fright, and nervous shock—24 per cent. of the admissions only were caused by such agencies as I have mentioned acting directly on the mind.

When we turn to the physical causes we find 6418 cases accounted for by them, 48 per cent. of the whole admissions being attributable to direct physical causes, such as intemperance in drink, or sexual and venereal disease.

¹ I have to thank one of the liquidators for kindly furnishing me with their report.

No doubt some of the physical causes are distinctly non-preventable, such as old age; but many of them are, and it is satisfactory to have something tangible, recognisable, curable, and preventable to go on. Taking intemperance in drink, it is put down as the exciting cause of insanity in 1351 of the admissions, the predisposing in 415—altogether it is credited with causing 14·6 per cent. of the whole admissions. Lactation as a predisposing cause affected 15, as an exciting 101; it caused 1·9, nearly 2 per cent., of all the female admissions.

Education, elevation of the mental faculties, a diffusion of knowledge as to the requirements of the bodily health, an acquirement of desires for rational amusements and intellectual relaxations, among the mass, have for long been pointed out as the preventive for insanity caused by giving rein to the baser passions and appetites. As this is long in coming, we must look for, hope for, urge as far as we can, and point out, as we as a profession have done, and are constantly doing, stringent and easily enforced legislation which will deal with habitual drunkenness, prevent the adulteration of malt and spirituous liquors, and the sale of newly made spirits which contain constituents especially deleterious to brain-tissue. Such legislation must be enforced to be of value; permissive legislation on such a subject is valueless.

Are doctors sufficiently consulted by heads of families either as regards bodily or mental health—in fact, as regards the prevention of disease in their offspring? Are they not in the majority of cases merely called in to attempt to cure a disease which has been long going on, and which might have been prevented?

With regard to children, I believe medical men are now more consulted than they used to be about their proper nutrition in infancy and childhood; but is sufficient attention paid to their education, recreations, the choice of a profession, the capacity of the mind for severe mental toil, the question of bodily disease, its development under certain conditions and in certain occupations, and its power of being retarded or prevented by constant attention to bodily health and freedom from mental strain? Are such subjects properly present before the minds of parents, guardians, and the medical profession at large? This is a difficult subject, and each year it is becoming more and more pressing; and when we look at the causation of many cases of mental disease we have the conviction forced upon us that had such and such a case been in different circumstances, it would have been most unlikely that he would have become insane.

Then, leaving the period of childhood and coming to that of youth and budding manhood and womanhood, should not the primary laws of physiology be taught? Would it not be well for those who hope to live for the allotted span in this world to know how they live, and how best to live to keep living? and some truths, of course in a guarded way, should be communicated to them by their elders about their reproductive systems, which to many, especially those of a neurotic family, is the cause of many uneasy feelings, wonderments, and doubts. From my experience, I am quite sure that in many individuals of both sexes evil practices and habits have often arisen in ignorance—habits such as masturbation, with its train of evil consequences to mind and body, excitement, vacillation, depraved inclinations of all sorts, in the male; and similar, if less marked, mental changes, with hysteria predominating, in the female, an unhappy ruined life and weakened body, at the slightest, and in extreme cases existence in an asylum, a trouble and a care to all, for in such cases, at their worst, impulsiveness is a prominent feature, and dangerous outbreaks of short, almost momentary duration alternate with depression. Such persons are usually filthy in their habits, and nearly always end in complete dementia, frequently run their bodily health down to the lowest ebb, and die of phthisis.

Then, passing onwards, is marriage at present looked upon in its proper light? Are the prospects of a healthy progeny considered? Wealth, social position, even creed, are duly thought of—why not mental and physical properties? Each year one hears of marriages broken off for monetary or social reasons, but is the family history of the young couple ever considered—the great probabilities of disease in one or both, the family home broken up by puerperal mania, the children descended from two insane or phthisically-inclined parents, causing anxiety, discomfort, grief, and useless regret, instead of happiness, bright anticipations, and increase of love; and when, by eating the fruit, the knowledge is gained to see that all this could have been prevented, that

knowledge acquired in time might have enabled one to guide their selection, and to influence their love, as well in matters of this sort as in those of monetary and social consequence.

It would almost seem as if there was an elective affinity between persons with a neurotic taint, especially those descended from suicidally disposed ancestors. I have often been led to notice how frequently they intermarry. They are often in the blush of youth well-developed and good-looking, arrive more quickly at maturity than their more healthily constituted compeers, have more adaptation of character, are more subject to the emotions, and probably being more deficient in the sterling qualities required in life's journey, yield themselves with more *abandon* to the pleasures of the moment, without a care for the morrow. I think that in this probably lies the fascination often noticed in such cases as I describe. But while the state I have presented occurs in some instances, and at the early periods of life, there is another side to be heard, and even the individuals who while they are young present cheerful aspects often get morbidly dull in the middle and later periods of life. There are many neurotically descended who feel their burden from the first, and feel it more so from their surroundings. To be descended from insane or even peculiar and eccentric ancestors is a great hardship, but to have to live with them and be surrounded with a large circle of similarly constituted relatives is nearly as bad, and undoubtedly has a bad influence on the young. That people unintentionally acquire peculiarities from associates is well known; that a dread of an outbreak of nervous disease is often present in the minds of those who inherit strong neurotic taint is also well known; and that this dread may be almost extinguished, or kept constantly on the alert by the surroundings, stands to reason. Persons with strong neurotic taint should, for their own safety and happiness, live as much as they can amongst healthily constituted strangers. They should, as far as possible, keep clear of the associations which constantly bring their unpleasant inheritance before them prominently. In many cases a change of county, or even of country, is really a great safeguard. This should be known.

Only when such evils take place as puerperal mania is the advice of the medical man asked for or listened to as to the probability of a recurrence of the malady at the next confinement, or as to the time which ought to be allowed to elapse before the woman is again subjected to the dangers of another attack. After a severe attack of puerperal insanity the nervous system must take a long time to recover thoroughly; and though the patient may ostensibly be well, and not need asylum or other treatment, yet I believe that a considerable period without any extra calls on the system generally is necessary for total and complete recovery. I always tell husbands my views in this respect when I discharge patients who have recovered from puerperal mania, and advise for their own comfort that a year should elapse before another pregnancy; but usually such advice is unattended to, and a quickly following confinement brings a recurrence of the insanity. The most marked case that has lately come under my notice was E. J.—. Father drowned himself. She had been always rather nervous. Came in on May 15th, 1877, labouring under puerperal mania. This was two weeks after confinement. She was excited for a long time, but gradually got better, and was discharged on March 11th, 1878. I expressed myself strongly to the husband, pointing out that in this case, from the family history, it was even more essential than in ordinary cases that a considerable interval should elapse before the next confinement. This patient was readmitted, pregnant, on Sept. 21st, 1878. She continued in a state of excitement during her pregnancy, and was confined of an apparently healthy male child on Dec. 15th, 1878, 288 days from her discharge, so that she probably became pregnant within eight days of leaving. She is still in the asylum, an excited, hysterical female, at present entirely devoid of self-control. Had she not become pregnant, I think that in all probability she would have retained her reason.

In nearly all the cases of insanity from over-nursing that come under my observation the patient has been nursing up to the time of being brought to the asylum. In the majority of cases, after the milk has been got rid of by rubbing the breasts with a saturated solution of extract of belladonna in glycerine and the administration of a saline aperient, and the patient afterwards treated with iron and tonics, recovery is very speedy, if the patients were warned about such an

occurrence as nursing proving too much for them, if the too great drain on the system were prevented by partially feeding the child or entirely ceasing nursing when the bodily health was seen to suffer and the patient was becoming dull, the attack might be averted. I have always thought that medical advice was too tardily sought in such cases.

The time between gestations, even when not followed by immediate insanity, does not meet with the consideration it merits. I frequently see cases of mental disease, in many complicated with phthisis, in which numerous and rapidly following pregnancies have undoubtedly been the cause; and in a considerable number of cases of middle-aged and oldish women, with lowered vitality, broken-down constitutions, absence of nervous power, and consequent dementia or melancholia, I have, on scrutiny, clearly realised that unduly rapid pregnancies or miscarriages have been the cause of such a state. And yet in cattle this is avoided; a breeder of good stock, always after a miscarriage, does not allow another pregnancy till the time he would have done so had the female gone the full time.

That fright, nervous shock, illnesses, and mental anxieties exercise in some manner a direct influence on the unborn offspring through the mother is well understood. Maternal influences during the period of gestation is the one subject of this class which has received most attention, and great care is usually expended on the interesting patient. Probably the laws of some of the nations who did away with weakly offspring gave the initial impetus to this attention, but I doubt whether much family happiness would not result by attention to the life, health, and habits of would-be parents during the period immediately preceding gestation. It is well known that frequently children procreated during alcoholic excess are imbecile or hydrocephalic. Deviations from health, both mental and physical, may be a question of degree. One frequently sees the children of intemperate parents stupid, dull, and coarsely formed. I have no doubt the mental state of the parents during the period immediately preceding procreation has a great influence on the future child. I should like to hear, as some day we shall, something as to the effects of the siege of Paris and the Franco-German war on the children procreated in Paris during that eventful period. In Jewish history newly married men were exempt from martial service.

I trust that the portion of my address which deals with the treatment of insanity will convince you that practitioners in this department, as in the others of our profession, have at heart not only the good treatment of the patients, but also the advancement of our knowledge of the subject.

As regards the prevention of insanity, all our profession are interested in it. I have brought before you the thoughts which have occurred to my mind as worthy of your consideration. Ours is a progressive study; it should end only with our lives. As each year rolls past we should have observed some new facts, made ourselves more acquainted with the wonderful laws of nature which have specially to deal with humanity, and fitted ourselves to advise with such certainty as is to be expected from fallible man on many of the points upon which I have touched, for each year more will be expected from us in this direction.

HUMAN AND ANIMAL VARIOLÆ: A STUDY IN COMPARATIVE PATHOLOGY.

By GEORGE FLEMING, F.R.C.V.S.,

ARMY VETERINARY INSPECTOR.

(Continued from vol. i., page 334.)

I HAVE already alluded to the results of small-pox inoculations on the horse, and shown that, as on the ox, they were either negative or nearly so, the positive results yielding only the most trifling evidence of infection, and nothing at all like horse-pox being ever produced from the insertion of the small-pox virus into the skin of the horse, while retransmission to mankind only gave rise to small-pox. On the contrary, as we have seen, horse-pox inoculated on the cow produces what in every way corresponds to cow-pox, or on man to vaccinia. From the cow and man horse-pox can be transmitted indefinitely, and while its action is modified by repeated transmissions, its protective influence

against variola is undiminished.* This has been demonstrated times almost without number, from the days of Jenner up to the present date. The most interesting and instructive of recent demonstrations in this direction is that recorded by Dr. Pingaud, in a communication presented to the Paris Academy of Medicine a few months ago. Having observed, with Drs. Viseux and Thomas, an epizooty of horse-pox in February, 1879, he determined to make some experiments, and selected as a vacciferous subject a four-year-old horse affected with the disease, but whose antecedents were well known, and whose health at other times was excellent. The cutaneous eruption was discrete; there were only a few crusts of pustules about the hollow of the pasterns; but in the mouth, and within the upper lip, the mucous membrane was studded with vesicles offering the characteristic nacrous aspect. Lymph was collected from these pustules with the greatest care, and seven young soldiers of the 10th Hussars, who had not been vaccinated, were inoculated. On the sixth day six of the men showed at the seat of inoculation the characteristic vaccine vesicles, which had a somewhat inflamed base. From four of the soldiers lymph was taken; with this sixty-four men—eight of whom had not been vaccinated—were inoculated. In forty of these the result was positive—60 per cent. successful vaccinations. With none of the patients were there any serious inflammatory symptoms, and only in a very small number did the inoculations assume a furunculoid aspect. Calves were inoculated from the horse, but the proportion of successes was only 48 per cent., rather going to prove that the virus became weakened in the calves.

I have stated that horse-pox and cow-pox are almost, if not quite identical in their effects, when transmitted by inoculation to man, the ox, or the horse. Chauveau inoculated five horses and two asses with animal vaccine from Naples; the youngest animal was seven years old, the others from sixteen to twenty years of age. For five and six days there were no signs, but in from five to eight days the seat of puncture became markedly papulous, the papules increasing in size until about the tenth day, when they were acuminated, had a very broad base, and were red, painful, and hard. From the ninth to the twelfth day was the period of secretion, the epidermis becoming slightly raised throughout the whole extent of the papule by an exudation of limpid citron-coloured serum; this dried into yellowish transparent crusts, very different in appearance from those of vaccinia in man or cow. The secretion from the lymph continued for several days, and ceased from the thirteenth to the seventeenth day. When the crust was removed there appeared a moist granular red surface level with the skin, but having a deep central cavity, a kind of umbilicus, in which had been fixed, like the head of a nail, the prominent under-surface of the crust. There was no febrile reaction. In the asses there was shedding of the hair and epidermis in various parts, with abundant serous exudation. As compared with its evolution in man and the cow, the vesicle or pustule was slower, and there was a difference in its shape and character, the pustule being acuminated, the lymph scanty, and the umbilicus small or altogether absent; though in an ass sixteen years old the pustule had from the commencement a central umbilicus. In the horse the crust extends over all the pustule, while in man and the cow only the centre is covered. In the ox the lymph is rarely abundant, and there is never anything more than a thin brown crust; but in the horse the crust is wide, thick, rough on the surface, and transparent and citrine-tinted.

SHEEP-POX.

Sheep-pox differs from cow- and horse-pox in having a history extending over some centuries, and in being closely allied to small-pox in its extension, this depending not only on its contagious but also on its infectious properties, and the eruption being more or less general over the body. Indeed, so far as intensity of virulence is concerned, its appearing in an epizootic form, as well as the serious symptoms and mortality accompanying sheep-pox, there is the closest resemblance between it and human variola. We have seen that cow-pox and horse-pox are far from being serious disorders, the affected animals, in the majority of instances, being

very little, if at all, disturbed in health, while the diseases are not infectious, and not always very contagious.¹

In the first portion of this paper I alluded to sheep-pox being mentioned at the Vaccination Conference, and observed that it was there admitted that the sheep had a variola of its own. On again looking over the report of that meeting, it appears doubtful whether the speaker who referred to it thought it was peculiar to the sheep, or whether it was not also derived from human variola. The best proof that it has no relation whatever to small-pox is to be found in the fact that it prevails continuously, and sometimes most extensively and fatally, in countries where small-pox is extremely rare, as in East Prussia; and in regions where the latter is never absent, and is often epidemic, sheep-pox is only known as an imported disease. In England it is never seen unless introduced from countries where it is enzootic. The terrible outbreak which ravaged our flocks in A.D. 1276, and continued twenty-eight years, was due to importation from France; and the appearance of the disease in 1847 and 1862 was due to foreign sheep. It has been unknown in the country since the latter date.

Notwithstanding the close resemblance of sheep-pox to small-pox (the pustules in the former being, however, acuminated, the course of the malady very similar, the complications the same, and the mortality as great), yet the one disease has no influence either in the production of or protection from the other. It appears to be finally established that human variola will no more produce sheep-pox than it will cow-pox, notwithstanding the close affinity between the two; and while variolation will not protect from sheep-pox, neither will inoculation with the virus of the latter prevent mankind having small-pox. Some authorities have denied that ovine variola can be transmitted to the human species, and the extreme rarity of cases of supposed accidental transmission certainly gives countenance to the opinion. But several instances are recorded, nevertheless, of veterinary surgeons, who have been accidentally inoculated with the virus, suffering from local and general disturbance, like that produced by vaccination.² Korner³ reports that a child who tended (barefoot) sheep affected with variola, had a number of discrete and confluent pocks on both feet. This transmission occurred also to one of Korner's own children. On the back of the boy was developed a pock, which finally became as large as a five-pfening piece; there was severe concomitant fever. The child appears to have been inoculated while Korner was charging some capillary tubes with sheep-pox lymph from a pipette, a drop of the fluid, it is supposed, having fallen on him.

Röll has unsuccessfully attempted to inoculate cattle with sheep-pox, and sheep with cow-pox; but Zundel⁴ has given an instance in which two cows were directly infected through cohabitation with diseased sheep. Haubner mentions that inoculation with small-pox matter has sometimes produced pustules on the dog and pig; but reinoculation from these did not cause the malady in sheep. Hertwig and Hering assert that the malady is readily communicated to goats in a true form, and may be transmitted from them to sheep. In the goat the pustules are usually smaller, and the general disturbance is less marked. But transmission is very far

indeed from certain, as goats very often associate with sheep without becoming affected. Hering knew of an instance in which fifty-four goats grazed with diseased sheep, and only ten became sick. According to Kersten and Gerlach, reciprocal inoculation of goats and sheep is always successful; and according to the observations and experiments of Gasparin, Dominick, Curds, and Spinola, and, still more recently, Gerlach, there appears to be a close identity between the variola of hares and rabbits and that of sheep, inoculations from one species to the other always yielding positive results.

When vaccination as a protection from small-pox began to gain ground as its benefits were becoming more and more evident, many of the leading veterinarians on the Continent tried it as a protective against sheep-pox, but they soon discovered that vaccinated sheep were as susceptible to their own particular variola as the unvaccinated. Verrier, Gohier, Husson, Voison, and other veterinary surgeons, found that, no matter how successful the vaccinations had apparently been, the sheep took the disease, either accidentally or experimentally, as readily as before. For this reason vaccination is never attempted now, as it does not confer immunity from sheep-pox—a curious circumstance with regard to inter-variola among different species of animals.

The contagium of sheep-pox is very active, as has been already stated. The observations and calculations of Chauveau with regard to the infectiousness of the malady, compared with that of vaccinia, tend to prove that animals attacked with sheep-pox will infect a hundred times more readily than those affected with cow-pox. The sheep-pox lymph also, according to the same authority, contains in an equal volume and weight a much more considerable number of virulent corpuscles, and is much more potent than that of vaccinia. He has shown that if the latter is diluted with fifty times its weight of water, inoculation with it is uncertain in its result, while the sheep-pox matter may be diluted with 1500 times its volume of water before it is reduced to the same condition. He has also demonstrated that the activity of this matter, like that of every other virulent substance, resides in the solid particles or elementary corpuscles held in suspension in the serum, which is not viruliferous; and that an equal quantity of sheep-pox lymph contains thirty times more of these particles than that of vaccinia.

(To be continued.)

ENDOCARDITIS FROM VERY SLIGHT RHEUMATISM.

BY CLEMENT DUKES, M.D. LOND.,
PHYSICIAN TO RUGBY SCHOOL.

I HAVE found mitral disease so often in healthy young persons, where there has been no history of rheumatic fever to account for it, that I have been at a loss to know how it has taken place, especially as it has occurred in those not accustomed to take violent exercise,¹ and who are thus not likely to have over-distension of the heart and orifices, or injured valves.

Visiting, as I do, daily 400 boys, among whom the slightest deviation from health is referred to me, I am able to see the beginnings of illnesses. The following case may be instructive.

On Feb. 17th, 1880, I saw Mr. H—, who complained of aching down the front of the thighs and slight pain across the loins; his pulse was quickened, and his skin hot. Thinking he had got wet, and so chilled, I sent him to the sanatorium to give him a hot bath, and put him to bed for twenty-four hours, in the hope that he would be quite well then. At night his temperature was 101.6° F., and pulse over 100.

Feb. 18th.—His aching in the thighs had gone; the loin pain, though still present, was better; temperature 99.2°, and pulse 100. He passed a comfortable day, and the only discomfort was the slight pain across the loins, but his evening temperature was 102°, and pulse over 100. I examined him most carefully, but could detect nothing more, and he had no albuminuria.

19th.—Temperature 100°, and pulse 100; but he said he

¹ Depaul believed horse-pox to be infectious, and cites, in support of his opinion, an instance in which a cow was inoculated with the lymph from the nostril of a horse, when seventeen other cows inhabiting the same shed were soon after infected, cow-pox pustules appearing on the udder and teats. In addition, a horse kept in a badly-constructed box in this stable, and breathing the same atmosphere as the cows, was also affected, the eruption showing itself on different parts of its body. It is not at all improbable, however, that the cow-keeper and his assistants, who handled the diseased and healthy animals alike, were the chief agents in spreading the malady. Indeed, the wife of the cow-keeper, in milking the cows, was vaccinated on one of her fingers, and yet continued to handle the teats of the others, notwithstanding the pain she experienced. Bouley has had perfectly healthy horses and cows cohabit with diseased horses, and when the malady was produced in them he was always able to trace it to direct contact. During the epizooty at Alfort, in 1863, it was possible to transmit the horse-pox to a series of horses by placing them one after another in a stall which had been occupied by a diseased horse. Each animal became affected in turn, and at times its immediate neighbours also; but beyond those in that stable there were no further transmissions, all the other horses remaining unaffected. As Bouley justly remarked, a really infectious disease does not comport itself in this manner. Veterinary Surgeons Turenne and Mathieu have also experimentally demonstrated that horse-pox is not infectious, and this is in accord with my own experience.

felt perfectly well. On the most careful examination I could find nothing else.

20th.—The same; but the boy could not understand being kept in bed when he felt perfectly well, and I could not sanction his getting up while his temperature and pulse were above normal.

21st.—After another careful and minute examination, owing to his temperature and pulse remaining the same, I detected a very soft and faint mitral systolic murmur.

This gradually increased in intensity every day, and on the 24th his temperature became normal, and continued so, but his pulse remained high for a time. He was kept quietly in bed for another ten days.

I carefully talked over the illness with his father, and told him he had endocarditis, which was a very serious matter; though by dint of the very greatest care, in not allowing any exertion for the next few months, its effects might all disappear; otherwise he would carry a maimed heart for the rest of his days.

On March 8th. he was unfortunately suddenly told he might go home for the rest of the term. Next morning when I saw him I was informed that he had been in a curious state, talking incoherently about things that had no existence at all, and he seemed thoroughly dazed at my visit. He was cheerful and happy, though incoherent, and had a quiet pulse. Whether his joy was too much for his state, or whether minute particles of fibrine were liberated from the mitral valve in the excitement of his sudden joy at the idea of going home, I cannot say; but I am inclined to think that this latter is what happened.

On June 11th I auscultated his heart, and there was not the slightest trace of murmur remaining. He was quite well.

The lessons to be learnt from the case, I think, are—1. That the most trivial amount of rheumatism may be accompanied by endocarditis. 2. That recent murmurs from endocarditis may and do disappear in young healthy subjects by dint of very great care while they are recent.

Rugby.

A CASE OF SUDDEN DEATH DURING ETHER ADMINISTRATION.

By ROBERT N. HARTLEY, M.R.C.S.

THE rarity of cases of sudden death during the use of ether as an anæsthetic is my excuse for entering somewhat fully into the following details.

The patient was a gentleman, aged sixty-six, who had for some weeks previously been the subject of symptoms which eventually culminated in complete obstruction of the bowels, the site of the obstruction being thought to be either in the lower part of the descending colon or the sigmoid flexure.

As the only procedure holding out any hope of prolonging life, it was decided, in accordance with the opinion of Sir James Paget and Mr. Pridgin Teale, and with the full consent of the patient, to open the bowel in the right lumbar region.

Before the commencement of the operation the patient was lying, or half-lying, in bed, with the head and shoulders well propped up with pillows, breathing regularly and without great effort. There was no complicating disease in heart or lungs, and the pulse, though rather quick and small, was not inordinately feeble. There was thus nothing to contraindicate the use of an anæsthetic, or to make one more than usually anxious as to its effect. Some artificial teeth worn by the patient had been previously taken out, and one of the pillows was now removed for the more easy adjustment of the inhaler.

Ether was administered by Clover's smaller inhaler, two ounces being the quantity contained in the ether-chamber. The patient took the ether without the slightest hesitation or resistance, moderately inflating the india-rubber bag with each expiration, and in two minutes was quite anæsthetic. He was now placed on his left side with the head lower, and in five minutes from the commencement of the administration of ether the line of incision was made by Mr. Teale. The patient was never allowed to become deeply "carbonised," and the inhaler was frequently withdrawn entirely. In ten minutes from the commencement of the operation, and

just as I was engaged in counting the carotid pulse, which was beating evenly and with a rather stronger impulse than before the operation, he showed an inclination to vomit, and ejected a quantity of brownish fluid smelling strongly of brandy. He then took one deep inspiration, and seemed as if inclined to vomit again; but his head sank back on the pillow, and he quietly died, making no further respiratory effort, except one short gasp during the performance of artificial respiration. Prompt exploration of the fauces failed to show any mechanical obstruction to the breathing, and in spite of an immediate resort to artificial respiration and all other available means for restoring animation, our efforts proved useless. An examination of the inhaler showed that a little more than an ounce of ether had been spent.

No post-mortem examination was made.

The interest of this case centres in the difficulty of defining the exact cause of death. The mode of death is one which unfortunately is not rare during the use of *chloroform* as an anæsthetic, but is almost unknown while a patient is under *ether*.

There was no mechanical obstacle to respiration by the regurgitation of anything into the larynx during the act of vomiting. Nothing solid had been introduced into the stomach for seven or eight days previous to the operation, and the vomited material consisted entirely of thin fluid. Moreover, there was no paroxysmal or convulsive seizure such as would be likely to follow a sudden mechanical interference with the act of breathing.

Two circumstances may have contributed to the suddenly fatal result:—

First, the distension of the bowels possibly interfering to some extent with the descent of the diaphragm, and hence with easy respiration, though neither before nor during the administration of ether had the patient shown any considerable difficulty or distress of breathing. Mr. Teale regrets, however, that he did not at once complete the operation, and rapidly open the bowel, and thereby reduce one factor—the distension by gas.

Secondly, the undoubted tendency to death from asthenia in cases of abdominal obstruction. In this particular case, the lungs having been more or less emptied of air by the act of vomiting, the additional quantity of blood drawn into the heart and large vessels by the next inspiratory effort might easily have brought the feebly acting heart to a standstill. Mr. Clover suggests to me that by the eructation of fluid containing brandy the ether may have been mixed with alcoholic vapour, which would add to its narcotising effect, and thereby tend to increase the cardiac depression.

Brixton-road, S.W.

ABSCESS OF THE CEREBELLUM.

By W. A. BERRIDGE, M.R.C.S., L.S.A.

I TRUST a general practitioner may be allowed to put upon record the following brief notes of a case of abscess of the cerebellum, as a small token of his gratitude for the instruction he received from Dr. J. Hughlings Jackson, F.R.S., and for the care bestowed upon his clinical education by his former teacher and now esteemed friend, Dr. Stephen Mackenzie.

A. D—, aged seventeen, had suffered from time to time since he was two years old from "gatherings in his head," which "broke," and "smelled very bad." He went to school when five years old, but never got on well. The schoolmaster said "he was stupid, and would not learn." Still he learned his letters, and could hold his own in play with other boys. He had no particular illness, never had scarlet fever, and had no signs of congenital syphilis, but often suffered from headaches and the aforesaid "gatherings."

When first seen (August, 1879) he was tall, pale, and rather thin. He spoke as I have noticed patients with organic cerebral mischief generally do, his words beginning with a "jerk" and ending with a drawl; or, in other words, the first part of a word being sharp and rather acute, the latter part grave and always prolonged. His mother said, "I have sent for you because he has a cold in his head, and cannot smell." On further inquiry, "he had headaches, occasional retchings, and felt giddy"; but he could not describe his "giddiness." He had no "reel." He ate ravenously. Urine 1015, acid, no albumen, no sugar. Temperature normal. He had no paralysis. Pupils dilated, but responded to light.

On examination with the ophthalmoscope, "the edges of both discs were rather indistinct, but there was nothing definite." After some treatment he improved, and was lost sight of for several weeks. When seen again (December 1879) his smell had returned, but he had lost his sight; he was quite blind. The edges of the discs were now quite obscured, the vessels partly covered by exudation; that is to say, he had well-marked double optic neuritis. He vomited frequently, and complained of intense pain at the back of his head. He had now the three cardinal symptoms—headache, vomiting, and double optic neuritis; he had also a long history of ear-discharge; so there was no difficulty in saying he had an abscess in his brain, and that he would die, most likely suddenly.

There was no marked change, and he died quite suddenly on March 12th, 1880. Next day, assisted by my friend and partner, Mr. F. B. Hallows, I opened the head. The convolutions were pale, and somewhat flattened. Nothing was noticed until slicing the cerebellum. There was a large abscess involving nearly the whole of the right lobe of the cerebellum, and containing about three ounces of what a surgeon would call "laudable pus." Permission could only be obtained to examine the head.

Redhill.

NOTES OF A CASE OF LYMPHADENOMA.

By W. BERRY, M.R.C.S.E., L.R.C.P. & S. ED.

HONORARY SURGEON, ROYAL ALBERT EDWARD INFIRMARY, WIGAN.

ON December 10th, 1879, I was asked to see Patrick O'B—, twenty-six years of age, a collier, living in a small house with deficient hygienic surroundings, and was given the following

History.—In August, 1879, he met with an accident in the coal-mine, being injured between two tubs and thrown on his back against the tram-rails. He was able, however, to walk to the surgery of the colliery doctor, who prescribed a liniment for him, which he applied. In consequence of this accident he was off work for one month; then he returned, working only one day, when he stated that he sprained his back owing to his work being heavy. He sought advice this time at the Wigan Infirmary, where he was admitted some time in September. He was discharged on the 9th of December without any improvement, feeling, if anything, weaker than when he entered.

Physical examination.—When I saw him in the evening of Dec. 10th he was lying on his back in bed, having a sallow, pasty appearance, with some puffiness underneath the eyes; respiration somewhat short and hurried; pulse 96, feeble; tongue slightly furred, with slightly raised papillae; and dryish, although he did not complain of much thirst; bowels slightly constipated, and appetite very poor; urine moderate in quantity, of high colour, with some lithates, but no albumen; respiration somewhat puerile, probably owing to its hurried character; no dulness on percussion; heart's sounds very feeble, especially second sound, which could not be heard distinctly, but no murmur. On examining his abdomen, in left iliac region was found a round hard swelling about the size of a large orange; this tumour was immovable, and seemed to increase in size at its base. The inguinal glands and femoral glands of both sides were hard and enlarged, but not painful. He complained of pain behind the abdominal tumour in his back, and attributed all his symptoms to the accident. I did not take his temperature, but the house-surgeon of the infirmary told me that when he was in that institution he had a temperature of 103° F. His wife informed me that he was strong and healthy previous to the accident, but after his death I learned he had not been in good health for some time. The man and his friends were anxious to have all his ailments put down to his accident, so that he might receive benefit from the Permanent Relief Society; hence the difficulty in obtaining a correct history and arriving at a true diagnosis.

I prescribed a mild aperient tonic for him, and ordered plenty of milk and nourishing food.

I saw him two and three times a week, but with no marked improvement in his symptoms. The pasty, puffy appearance of his face increased, his left leg and thigh became cedematous, bed-sores commenced to form over his hip and great trochanter, and the femoral glands enlarged. His breathing got more impeded, and debility much greater.

On Jan. 7th, 1880, the glands just above the clavicle on the left side were much enlarged and almost in one mass, and the posterior triangle of the neck also contained glands enlarged in size.

No history of syphilis could be made out. I came to the conclusion that we had a case of *lymphadenoma* to deal with; through neglect, however, a microscopic examination of his blood was overlooked, but the æmic appearance of his face was sufficient evidence of impoverished blood. He gradually got worse and died on Jan. 18th.

Through the kindness of the coroner, I got an order for a post-mortem examination, owing to the deceased's relatives seeking to obtain pay from the Permanent Relief Society. On January 20th, at 8 P.M., sixty-two hours after death, with the aid of my assistant, Dr. O'Reilly, and my pupil, Mr. Richards, I made a post-mortem. The body was emaciated, with swellings of enlarged glands in the neck, inguinal regions, and left side of abdomen, cedema of the left leg, a small bed-sore over left trochanter major, hæmorrhagic congestion over the buttocks and lumbar vertebræ.—Head: On removing the calvaria, the dura mater was found to be slightly adherent, the brain-surface (convolutions) pale, the arachnoid filled with serous fluid; when cut into it showed the same absence of blood; serum was also found filling both lateral ventricles.—Chest: Lungs in a state of collapse, lying at the bottom of the thorax, the pleuræ being filled with fluid. Lungs, on removal, found to be adherent in places. Heart lying flaccid in the pericardium, which contained very little fluid; on opening its cavities very little dark-coloured blood was found in them; the valves were healthy.—Abdomen: The liver was prominently in view, extending over into the left hypochondriac region, being much enlarged, but healthy in appearance when cut into. The spleen weighed about six ounces, but did not appear diseased. The stomach was distended with gas, as were also the intestines. The coats of the stomach were somewhat thinned, but not to any marked extent. The kidneys were normal in size, capsules easily removed, but the cortical portions thinned, otherwise healthy. On pulling over the small intestines and mesentery, there was found lying on the left side of the bodies of the two lower lumbar vertebræ a solid mass, firmly adherent. I removed a good portion of this tumour with the knife for subsequent examination; it was about the size of two kidneys, and was outside, but enveloped by, the peritoneum. A number of enlarged glands were found on the under surface of the mesentery, about the size of buttons, and these passed down chain-like into the pelvis, along the rectum, being larger on the left side. The glands in the femoral canal were also enlarged. The bladder was healthy.

A MIRROR OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proæmium.

WEST LONDON HOSPITAL.

A CASE OF HÆMORRHAGIC DIATHESIS; HÆMORRHAGE FROM THE MOUTH; DEATH.

(Under the care of Dr. THOROWGOOD.)

FOR the following notes we are indebted to Mr. Sidney H. Lindeman, house-physician.

William A—, aged eighteen, fairly well nourished, but presenting a strumous and anæmic appearance, and who for some time past had lived badly, was admitted on July 9th, 1880. He first attended as an out-patient on July 8th, and stated that on July 4th about 3 A.M. he found that he was bleeding from the gums. This lasted for about four hours and then stopped, but reappeared shortly before coming to the hospital. He had never, he said, noticed it before, but had been subject to profuse hæmoptysis, and at times had found "large blue lumps" on the chest, over the sternum, coming without any cause. These swellings lasted a few days, and then disappeared. He had never had any hæma-

temesis or melæna, nor, to the best of his belief, any effusion into the joints. He volunteered the statement that four of his relations had died of the same thing, but did not know what relationship they bore to him. This made him extremely anxious. He was ordered a gallic and sulphuric acid mixture, and a mouth-wash of alum. This seemed to have had a slightly beneficial effect for a time, but the bleeding returned as bad as ever the following morning (July 9th).

On admission a physical examination revealed a soft systolic murmur at the apex of the heart. Blood was oozing freely from the gums of the upper jaw on the right side. A mixture of iron and the liquid extract of ergot was ordered, and a mouth-wash was given containing equal parts of the tincture of perchloride of iron and water, and the patient was encouraged to suck ice freely. The bowels had acted well. He was put on a liberal diet, which he seemed to take with relish. The hæmorrhage, however, abated little, if anything. The same evening counter-irritation was tried to the back of the neck, but without any perceptible advantage.

On July 11th he presented a ghastly appearance. He had had a very bad night, and after dozing a little had vomited black discoloured blood at intervals. The hæmorrhage had not ceased for a moment. On examining the mouth, the blood seemed to be now coming with a pulse-like motion from the gums of the last two upper molars on the right side; it was watery-looking, and gave the impression of its being arterial. The man had no pain in any of his teeth, which were all sound and of exceptional whiteness. Considering the urgency of the case, it was thought that the actual cautery might be applied with advantage. Accordingly, Mr. Wright, the house-surgeon, passed the cautery along the bleeding surfaces on both sides of the teeth. This produced an eschar over the place; but the gums of the adjoining teeth now began to bleed. Lint soaked in a solution of the subsulphate of iron was now freely used, and the hæmorrhage was completely stopped for about one hour. At 3 P.M. it returned again from the mucous membrane of the cheek and the whole line of gums. The patient was now thoroughly exhausted, presenting a blanched and haggard look, and complaining of pain in the chest and epigastrium. A linseed-meal poultice was applied with relief, and the subsulphate of iron used as before, this time, however, with not such a happy result. Constantly vomiting altered blood and rapidly becoming weaker, he was at last unable to retain the nourishment necessary to sustain life, and died exhausted at 2 A.M. on July 12th.

CROYDON GENERAL HOSPITAL.

OVARIOTOMY; RECOVERY.

(Under the care of Mr. HENRY HORSLEY.)

FOR the following notes we are indebted to Mr. J. J. Newman, house-surgeon.

M. P—, aged forty, unmarried, had been under observation as an out-patient for some months previous to being admitted on Jan. 27th, 1880, for the purpose of undergoing the operation of ovariectomy. Her general health had been good two years before she first noticed that her abdomen was increasing in size; this was most marked in the right side. The swelling slowly progressed, and latterly she had experienced much dragging pain, chiefly in the right groin, and was felt more particularly when lying on her left side.

On admission she had the anxious and pinched expression so often seen in ovarian dropsy. She was of a rather spare habit, but her body was well nourished, and the excretions were normal. Menstruation was regular, and had never been very excessive. The greatest measurement over the tumour was thirty-four inches. There was dulness on percussion, and fluid vibration was perceptible, but not very well marked.

As the ovarian cyst appeared to be free from any extensive adhesions, it was thought to be a proper case for ovariectomy, which was accordingly performed on Feb. 18th. The patient was put under the influence of chloroform, as the bichloride-of-methylene apparatus was found to be out of order. The operation was performed antiseptically, thymol being used in the steam spray. The abdominal incision was five inches in length. The tumour was readily reached, and found to be free from adhesions. It was tapped with

one of Spencer Wells's trocars, the fluid being of a thick gelatinous consistence, having a greenish-yellow appearance. The pedicle, about an inch and a half broad, was transfixed with a needle, and the two halves were tied with a ligature of carbolic Chinese twist, No. 4 size, the ends of one of the ligatures being made to encircle the whole pedicle, which was then divided. The ligatures were cut off short, and the stump dropped into the abdominal cavity. The sponges used to clean out the peritoneal cavity were soaked in carbolic acid lotion (1 in 40). The external wound was closed by four silk-worm-gut sutures, which had been soaked in the carbolic lotion; the sutures were passed from within outwards, the peritoneum being included. Two superficial sutures of carbolic Chinese twist were inserted at the lower part of the wound; hyaloderma smeared with vaseline was placed over the incision, overlaid by pads of thymol and carbolic gauze, which were fixed with strapping and flannel binder. The patient was then removed to a warm bed in the same ward in which she had been operated upon, there being no other patient in the ward.

She made a good recovery, the temperature never rising higher than 99° F., and pulse never exceeding 96. She was sick several times during the night of the operation from the effects of the anæsthetic. The catheter was used regularly for the first eight days, and a hypodermic injection of morphia given nightly for the first week, during which time she was fed upon iced milk, beef extract, and a very small quantity of brandy. The wound healed by first intention, not a drop of pus being formed. On the eighth day all the sutures were removed. The bowels not having acted, warm soap-and-water enemata were used. She menstruated nine days after the operation naturally and comfortably. She left her bed in three weeks, and was discharged from the hospital in five weeks and a half, with an abdominal support. On July 10th she was in perfect health.

The tumour consisted of two communicating cysts—one large and the other much smaller.

MANCHESTER ROYAL INFIRMARY.

CHRONIC SYNOVITIS OF KNEE-JOINT; ASPIRATION OF JOINT.

(Under the care of Mr. HEATH.)

FOR the following notes we are indebted to Mr. Oliver Withers.

Annie G—, aged twenty-three, weaver, fair complexioned and well nourished. She began to suffer great pain in the right knee about three years before, and swelling then set in. The knee, however, neither looked red nor felt hot, but the pain continued, and became very acute, especially when she tried to walk. The swelling remained with but little variation in amount up to the time of admission. She had always had good general health. Had no recollection of injuring her knee, though she was often obliged to kneel for long together in her work. There was no history of rheumatism, and there was no evidence of struma.

The right knee-joint was swollen, the swelling chiefly affecting its upper part. There was distinct bulging on each side of the quadriceps tendon, and fluctuation was clearly felt across the joint. The knee felt of normal heat, and there was no redness of the skin. Night-pain was very acute within the joint, though there was no tenderness or pain when the sole of the foot was struck. The synovial membrane felt thickened, and the joint-cavity was evidently distended with fluid. Temperature normal.

On May 25th Mr. Heath aspirated the joint under the carbolic spray by pushing in the trocar on its outer side about one inch and a half external to the margin of the patella. About three ounces of a thin, dark straw-coloured fluid were removed. The wound was then dressed antiseptically, and the limb placed on a back splint, with a foot-piece to ensure rest to the joint. The next day the patient was quite comfortable, having slept soundly through the night. Temperature normal.

The leg was left untouched until June 1st, when the dressings were removed for the first time; the wound had quite healed, but there still remained some slight pulpy thickening in the joint.

On June 8th Scott's dressing was applied with a starch bandage over it. The knee was still painless. The temperature never rose above the normal line during the whole time she remained in hospital, and the pain was completely relieved by the operation.

ACUTE SUPPURATION OF KNEE-JOINT; ASPIRATION.

Martha V—, a thin, pale, delicate-looking woman of twenty-seven, had suffered with a swelled and painful knee for about a month. She had no recollection of having injured the knee, but her attention was attracted to it by the severe pain she felt in it, and she found a slight swelling on one side of the patella. This quickly increased in size until it spread over the whole joint, which became very hot and tender.

On her admission (May 17th) the knee was very swollen, hot, red, and painful. There was great bulging over the inner part of the joint, and the skin was very tightly stretched over the contained fluid, and was of a deep red colour. The knee was slightly flexed, and she kept it perfectly quiet on account of the acute pain which the slightest movement brought on.

Mr. Heath determined to aspirate at once. This was done under the spray, and five or six ounces of a sero-purulent flaky fluid were withdrawn. The limb was dressed like the former case. Axillary temperature 100° 6'. When the dressings were removed next day three ounces of pus escaped. Temperature normal; no pain. The limb remained bandaged after being dressed a few times from the 25th of May to the 2nd of June, when the wound was found to have healed. The joint was quite painless, and there was no return of swelling or other inflammatory symptoms. Patient left hospital with some joint-movement on June 18th. The temperature in this case after operation never rose above 99° 2', and from the sixth day to the end of the time was normal.

SHEFFIELD GENERAL INFIRMARY.

CONTUSED WOUND OF KNEE-JOINT: SUPPURATION; RECOVERY.

(Under the care of Mr. JONATHAN BARBER.)

FOR the following notes we are indebted to Mr. Charles M. Goyder, late house-surgeon, now senior house-surgeon at the Newcastle-on-Tyne Infirmary:—

J. G—, aged twenty-one, grinder, was admitted on Oct. 27th, 1879, suffering from contused wound of the left knee. He said that whilst grinding, the stone flew to pieces, and the sharp edge of a heavy fragment struck the outer side of the left knee-joint.

On admission there was a wound one inch in length, and transverse in direction across the outer side of the left knee-joint, in the interval between the external semilunar cartilage and the external condyle of the femur, completely severing the outer fibres of the ligamentum patellæ. On cleansing the wound, which contained much grit and dirt, the synovial membrane was found to be divided, and the cartilage covering the external condyle scored and abraded. There was no bleeding, but synovia escaped freely from the wound. The patient's general condition was good; pulse quiet. There were no symptoms of shock. The urine was healthy. The patient did not complain of much pain, walked to the infirmary, and was with difficulty induced to stay.

The wound was carefully cleansed at once, and the patient removed to bed. The joint was syringed out with a 5 per cent. solution of carbolic acid, a drainage-tube was inserted, and the usual antiseptic dressing was applied under the spray. The limb was placed on a back splint. Milk and beef-tea, together with perfect rest, prescribed. The evening temperature was 100° F. Next day there was a plentiful serous discharge, but the wound looked well. Morning temperature 99°. On the 29th the wound looked angry and tumid. The discharge was copious; the dressings were fetid, and at Mr. Barber's request were replaced by poultices of linseed meal. On the 30th pus was escaping freely. The morning temperature was 103°. There were great swelling and redness around the joint, with œdema of the limb above and below, and the man complained of intense pain with startings at night.

From this time the patient's general condition grew worse. Hætic supervened, and was soon followed by large abscesses in the substance of the thigh, but by none below the knee-joint. There was rapid emaciation; the tongue

was red and small; the pulse rapid and easily compressed. There were frequent rigors, the temperature varying from 102° or 103° in the evening to 99° in the morning. There were headache, sleeplessness, vomiting and purging, and great general depression.

The abscesses were evacuated through drainage-tubes. Chinchona with ammonia was administered internally, together with liquid nutritious food and a stimulant (brandy). Morphia was administered hypodermically to relieve pain.

The general condition gradually improved, through a long but steady convalescence. He was allowed to take solid food, with one pint of beer daily. At the same time he was put upon a McIntyre's splint, in order that as ankylosis took place the limb might be slightly flexed at the knee-joint.

Ankylosis gradually took place, and on March 18th he became an out-patient, with a firm, useful limb. On May 20th he was seen, and stated that his leg was perfectly firm, and becoming daily more useful to him.

KNEE-JOINT DISEASE; EXCISION; RECOVERY.

(Under the care of Mr. J. BARBER.)

S. K—, aged twenty, admitted Feb. 6th, 1880, suffering from disease of the left knee-joint. She stated that fifteen years before she injured the left knee by a fall, and that the limb had never been properly useful since, although she had continued to work and do some amount of house-work.

On examination the knee was seen to be swollen and bulged laterally; it was hotter than the right. The limb was straight, and only very slightly shorter than the opposite one. There was fluid in the joint, and the ends of the bones were expanded. Upon moving the limb flexion and extension were found to be limited, though the patella was free, and there was no grating. Lateral movements showed the ligaments to be relaxed. The heart and lung sounds were normal and the urine was healthy.

On March 10th, under antiseptic precautions, Mr. Barber excised the left knee-joint. The bone ends were found soft and diseased, and were freely removed; the synovial structures were thickened and pulpy, and they also were removed. There was very slight bleeding, and a drainage-tube was inserted between the bones, on a level with the extremities of a horse-shoe-shaped incision. The limb, after having been dressed, was placed upon a back-splint with an interruption opposite the knee. Milk diet was ordered. At 6 P.M., as considerable oozing had taken place, the wound was dressed by Mr. Kirsopp, assistant house-surgeon. Evening temperature, 99°.

Next morning the wound was dressed again and was doing well. There was no pain. The drainage-tube was removed and cleansed. Morning and evening temperature 98° 4'. On the 16th the wound was dressed. There were no signs of inflammation; the discharge was serous. On the 22nd the wound was healed, except at the opening for the tube.

On April 20th there was no motion laterally, and so far no inflammation or its results. The tube had been gradually shortened.

On May 12th the wound was entirely healed. There was good firm union, although not bony. Temperature throughout the case 98° 4'.

On June 5th the limb was placed in a starch bandage, and the patient was allowed to move about and get up. She complained of no pain, and felt perfectly well.

On July 29th the patient was going on extremely well, and although true bony union had not yet taken place, the knee was quite sound, and movement becoming less.

BELFAST ROYAL HOSPITAL.—The last Sunday in November is appointed for a general collection in Belfast in aid of the funds of the Belfast Royal Hospital, instead of the last Sunday in the year as heretofore. The employees and staff of the Brookfield Linen Company have contributed the very handsome sum of £40 18s. 5d. towards the funds of this charity.

A DEARTH OF WATER is threatened in the Clyde district. Greenock is stated to have only a thirty-six days' supply in store; and at Dumbarton, should the consumption be at the usual rate and the drought continue, the stock of water, it is feared, will be exhausted in less than a fortnight.

Reviews and Notices of Books.

Cours de Thérapeutique, professé à la Faculté de Médecine.
Par ADOLPHE GUBLER. Paris: Baillière.

THE name of Professor Gubler is probably not much known in this country, but few recent French physicians have inspired more affectionate regard and esteem among their pupils, or have at their death been more lamented. His last course of lectures was completed in July, 1878, and since his death they have been published under the supervision of Dr. Bordier. They have, however, been given to the public unaltered, from the shorthand notes of one of his pupils. The volume fully maintains its author's reputation. It is clear and fairly concise in style, and exhibits a wide knowledge of facts, old and new. The lectures possess, however, a characteristic which is very common at the present day in French medical literature—an endeavour, by extensive generalisation, to include all facts under general laws in a firm, if courteous, dogmatism, which does not like, and often will not tolerate, differences of opinion.

The work is not a systematic treatise on Therapeutics, but rather a sketch of the general principles of the action and use of remedies, illustrated by examples, some of which are given in considerable detail. Some general considerations on the nature and effects of remedies occupy the first four lectures. The various modes by which they are introduced are described in the next seventeen lectures. Four are then devoted to a consideration of the changes which drugs undergo in the system; and in the remaining lectures are discussed the modes of elimination of drugs, and the question of their antagonism. Drugs constitute but a part of our therapeutic arsenal, and the author's first task is to draw the necessary distinction between remedies and medicaments. He insists, with justice, on the therapeutical importance of many remedies which are not usually noticed in a survey of the subject. Foremost among these are moral agents, in which are included amulets and homœopathy—"encouragement and clear water" constituting the essential muniments of the latter. The mechanical and chemical effects of drugs are next glanced at, and the author then discusses the *modus operandi* of the large class of agents which do not act in either of these ways. Many drugs and articles of diet are capable of producing a profound effect even when given in small quantity. The theory is advanced that their operation is by yielding force to the system. The argument is based on the analogy of the liberation of force (heat, light, &c.) by substances in changing their state, and it is urged that no other theory is conceivable. It must be confessed, however, that the direct evidence in support of this theory is very small. Of an explanation of the action of many agents, as alcohol, coffee, &c., that they spare the tissues by lessening tissue consumption, Professor Gubler speaks in terms of contempt, but he brings forward no destructive evidence. Much as there is in physiology which cannot be explained by the known facts of mechanics and chemistry, there is even more that is thus inexplicable in pharmacology and therapeutics. The addition to the "radical forces" of the organism is regarded as the essential action of tonics, and stimulants are distinguished as agents which merely excite the evolution of the force furnished by the tissues. The ultimate effect is the same, the path by which it is reached is essentially different. The one increases, the other lessens, the force-producing power. The action of small and of large doses of strychnia is given as an example of this difference. The idea is, of course, that which underlies the name of "tonic" and "stimulant," but it may be doubted whether modern physiological knowledge should not make us hesitate before accepting it. That a simple stimulant may act ultimately

as a tonic, the effect of muscular exercise, voluntary or that artificial exercise which is produced by galvanism, abundantly shows; and it may well be that many true tonics are purely stimulant in their mode of action. The elective action of drugs on different parts is explained partly by their mode of elimination, and partly by analogues of chemical constitution between the drug and the tissues. The former explanation does but push the mystery a little further back, while the latter, supported though it is by the opinion of Liebig, rests on so small a basis of even presumptive evidence that it seems better to confess our ignorance than to attempt a dogmatic explanation.

In considering the medicinal substances which are drawn from the vegetable kingdom, M. Gubler directs attention to the remarkable illustration which they present (and which many inorganic drugs present likewise), that their influence has no relation to the constituents, but depends on the proportion and mode of arrangement of their elements. Drugs which are inert and those which are most potent are composed for the most part of the same elements. Their different action depends on the way these elements are grouped; as, for instance, we see in the similarity of combination in all the anæsthetics. Moreover, the most potent of the constituent elements—nitrogen—seems to render the compounds less active. Atropine contains less nitrogen than morphia; morphia less than theine. A still more striking instance of the effect of combination is afforded by arsenic, which, so potent a poison in an isolated form, is powerless when combined in cacodyl. Thus a slight change in constitution may profoundly alter the action of a drug. The beautiful discoveries of Fraser are quoted in illustration of this. The substitution of a molecule of ethyl for one of hydrogen in strychnia converts the most powerful tetanising agent known into one which paralyses the muscles, and thus we are able to understand how it is that the source of curara and of strychnia is almost the same.

The method by which medicaments are introduced into the system constitutes the next topic. The necessity there is that the substance should be in a liquid state is provided for, to some extent, by the solvent powers of the digestive juices, and of this one of the most important instances has only recently become known—the solvent power of albumen, contained so abundantly in the mucus of the alimentary canal, and which can dissolve even metallic mercury. But this method of administration has its disadvantages in the gastric irritation which many drugs occasion, and in the interference which they cause with the digestive process. An instance of the latter is furnished by some experiments with phosphorus. Having noticed a disturbance of digestion when phosphorus was given with food, M. Gubler obtained some gastric fluid from the dog by means of a biliary fistula. He placed some in a series of tubes with pieces of meat, and to some of these he added powdered phosphide of zinc. In a certain number of hours the tubes which contained only meat and gastric juice remained unaltered, while in those to which the phosphide of zinc had been added the meat was softened, browned, and half transparent. He has suggested an ingenious method by which the gastric irritation may be avoided and drugs kept from contact with the mucous membrane until the intestine is reached. This consists in enveloping them in fatty matter which is not acted upon in the stomach, but which becomes removed and absorbed when it reaches the intestine. It has been proposed to administer bile in this way when the secretion of the liver is deficient.

Into M. Gubler's discussion of the advantages and disadvantages of the introduction of remedies by the other mucous surfaces we cannot follow him in detail, but may mention one or two of the points on which he lays special stress. The statements which have been made regarding

the absorptive power of the mucous membranes of the bladder and vagina are singularly contradictory, but are reconciled by the different conditions under which the observations have been made. In health the absorptive power of these surfaces is very small; in disease it is very active. Hence, under the conditions in which we most want the local effect of remedies, we may apply them without hesitation, if they are not deleterious to the general system. Of all the mucous membranes the most active can be utilised only for vapours—that of the lungs. Some instances mentioned of the absorptive power of the lungs for liquids deserve to be better known. It was found at Alfort that from ten to fifteen litres of water introduced into the lungs of a horse were absorbed with great rapidity. Indeed, a constant current of water might be thrown into the air-passages, and the animal might die from the effect of the water on the blood and tissues, and yet the lungs after death be found free from water. These and other facts furnish a rational basis for the introduction of atomised liquids by the lungs, and even, within restrictions, of atomised solids. These subjects are discussed at length, and very ably, in the pages of M. Gubler's work.

An interesting chapter is devoted to the question of the administration of drugs through the undamaged skin. The experiments which have been made as to the absorption through the skin are carefully examined in the light of the author's own investigations. The facts that iodide of potassium is not absorbed from a bath, while a solution allowed to dry upon the skin is absorbed, are at first sight contradictory. Their reconciliation is found in the law that watery solutions are not absorbed, but that volatile substances do enter the system through the skin, apparently by their power of diffusion into the glands. If iodide of potassium is allowed to remain in contact with the skin, it is decomposed by the fatty acids, and the iodine thus passes in. Moreover, fatty substances are readily absorbed by the sebaceous follicles, and may carry with them substances which are dissolved in them, or which are in a state of fine suspension. The secretion of the sebaceous follicles, which facilitates this, hinders the absorption of watery solutions just as an oiled filter allows fat to pass through, and does not allow the passage of a watery solution which may be mixed with the fat. Thus many liniments, the basis of which is oily, are effectual. Moreover, the absorption is favoured by substances, such as chloroform, which can dissolve fatty matters, and therefore the secretion of the sebaceous follicles. The absorption of volatile, non-fatty substances is most active where the sebaceous glands are fewest, as in the axilla and groin.

The hypodermic method of administration receives its full share of attention, no less than five lectures being devoted to history, methods, application, theory, and dangers. The facts, admirably described, are for the most part well known. The author's opinion on the much-discussed question of the relative value of local injections—i.e., made into the part which is the seat of the disease—is worthy of note. His experience of the use of the hypodermic method is so large that his opinion on this point deserves special weight. It is strongly in favour of injection into the seat of the disease. The facts adduced in support of this view are, if well observed, conclusive. He states that in patients suffering from the rare condition of double sciatica the pain in the leg into which the injection is made is relieved far more than that in the other, and that this observation may be made alternately on either leg. Another interesting observation relates to the diminution of sensibility often to be noticed around the seat of the injection. He has observed this with injections of various substances, and uniformly when water only was injected. He attributes it to the hydration of the cutaneous nerves in their subcutaneous

course. It passes off when the local excess of water is removed. To this action the effect of injections of pure water is to be ascribed. He relates the case of a patient in whom he frequently substituted an injection of water for one of morphia, always with the effect of temporarily relieving the pain, which returned, however, much sooner when water was injected than when morphia was used.

The next four lectures are devoted to a consideration of the modifications which drugs undergo in the organism, illustrated by a lengthy and detailed study of the action of arsenic, in which, however, there is little that calls for special notice. Of more interest is the subject of the elimination of medicines, which is next examined at length. The faculty of generalisation, here as elsewhere throughout the work, carries the author into positions which are, we will not say untenable, but certainly less impregnable than their mode of statement would imply. For instance, he finds an explanation of a large class of facts in regard to the action and elimination of drugs in the relation which they bear to the constituent elements of the tissues. "Drugs are rejected the more rapidly, the more widely they differ from the normal components of the organism." Bernard has shown that the salts of potash are not tolerated so well as those of soda; they are indeed "muscular poisons." This is because there is little potash normally in the blood. Hence the potash is not expelled from the blood. The muscles contain normally much potash, and hence the potash in the blood accumulates in them in an excess which interferes with their nutrition. In the case of other salts the action of the same law is seen. Chlorides are better tolerated than bromides, and these than iodides, "always for the same reason" that the chlorides are in abundance in the organism, and hence are eliminated more rapidly. "Tolerance or intolerance for a substance is explained by its homogeneity or heterogeneity with regard to the organism which receives it." The reader will probably hesitate to accept the "law" as the sole explanation of the facts, and his hesitation will not be lessened when he reads, two pages further on, of some facts which are scarcely reconcilable with it (although the author appears unconscious of this)—namely, that iodide, bromide, and chloride of sodium are eliminated twice as slowly as the corresponding salts of potash, and that the same is true of the carbonates of soda and potash respectively. In truth, our knowledge of the action of drugs and the physiological chemistry of the tissues will probably have to be much more extensive before we can formulate the laws on which their elimination depends. We have not space to follow the author in his discussion of other facts relating to the elimination of drugs, and to their accumulation in the system.

In the final lectures the subject of the antagonism of medicines is very ably discussed, but on this subject we must refer the reader to the work itself. It will well repay perusal. As a guide to students, the small field which it covers, and the large amount of hypothesis which it contains, render it scarcely suitable. The teacher of therapeutics, however, will be rewarded by its study, on account of the extensive knowledge of facts, many of which are unfamiliar, the quickness to seize the relations of those which are apparently distant, and the long experience, which it displays.

Headaches; their Nature, Causes, and Treatment. By WILLIAM HENRY DAY, M.D., M.R.C.P. Lond., &c. Third Edition. J. & A. Churchill.

WHEN a work reaches a third edition, it may claim to have justified its author in writing it, and to be pretty independent of reviewers. There have been many previous works on headache, but it is to be admitted that Dr. Day writes at some advantage over his predecessors, inasmuch

as he is in possession of a deeper physiological knowledge of the problems involved in headache than was possible before the researches of Bernard, Ferrier, Jackson, and others. We are not yet, however, in possession of any such physiological knowledge as will enable us to comprehend all the mysteries of headache, or to know why one person's head is so constituted that it is more easy to say when it is not aching than when it is, and another's is so constructed that it never aches at all; why one person's headache always occurs on a Monday, and another's on a Friday, both of which are within our clinical experience. We are not yet ripe for any strict pathological theories of headaches. Dr. Day wisely says that "*he has relied rather on the investigation of facts as presented by the record of cases, than trusted to plausible theories.*"

In successive editions we should advise Dr. Day to discard theories even more freely than he has done, and all but strictly clinical classifications of his subject. By so doing he will still further simplify it. Some of his chapters seem tautological; as, for example, when he devotes one chapter to headache of cerebral hyperæmia, another to congestive headache, and another to plethora and increased vascular action. He describes no less than thirteen kinds of headache, exclusive of a chapter on headaches of childhood and early life, in which he mentions seven kinds of headache. It is, of course, difficult to discuss headache by itself, and to attempt to do so requires some justification. But it is so conspicuous and "commanding" a feature of human suffering that physicians may well be excused for giving it special consideration, though no better illustration could be adduced of the impotence of "specialism" than when it attempts to separate and to treat headache as an isolated disease. Dr. Day takes no such limited view of his subject, but, as a practical physician, regards it in the light of his patient's age, circumstances, history, and diathesis; he brings to bear upon it a large amount of experience and medical knowledge, and makes many therapeutical suggestions of much value.

On Preservation of Health in India. A Lecture, addressed to the Royal Indian Engineering College at Cooper's-hill, May 17th, 1880. By Sir JOSEPH FAYRER, K.C.S.I., &c.

THE object of this lecture was to give to the young men educated at Cooper's-hill such information about the climate, mode of living, diseases, and means of preserving health in India, as would be likely to prove useful to them in the peculiar circumstances under which they are placed on commencing their service in that country. It appears that there has been a great amount of sickness among the young engineers who have gone out to India, and that much of it was of a preventable character, and might have been avoided by a very moderate amount of information as to the mode of life to be followed on first arrival in the country, and the best course to be taken to meet the first symptoms of illness. To remedy as far as possible the effects of this want of knowledge, Sir Joseph Fayrer was requested to deliver this lecture. In it he has given a brief sketch of the climate of the various parts of India in which the engineers are employed, and has pointed out the more prominent causes of disease and the best means of counteracting them. The latter may be briefly summarised as—Lead regular lives, avoid excesses of all kinds, take regular exercise, keep the bowels open, wear flannel, and as far as possible avoid exposure to the sun. He has also given a short description of the most prevalent diseases, and the measures to be adopted until medical aid can be obtained; and an interesting account of the effects of snake-bites, and how to treat them—a subject upon which he may be justly considered the highest authority. The lecture cannot fail to prove useful to those to whom it was addressed; but we would suggest to Sir

Joseph Fayrer that he would confer a still greater benefit upon them if he made it the groundwork of a short handbook on the subject, prepared with special reference to the work upon which, and the circumstances under which, the Civil Engineers in India are employed.

New Inventions.

EXPLORING ASPIRATOR.

MESSRS. ARNOLD have made for Dr. Hensley of St. Bartholomew's Hospital an exploring aspirator. It consists essentially of a syringe in combination with a cannula and trocar; the cylinder of the syringe being prolonged into a fine cannula, while the piston-rod is continuous with the trocar, so that the retraction of the trocar and of the piston causing aspiration is by one movement. The cylinder of the syringe is a glass tube fitted with similar screws at both ends, one of which fastens into the collar of the piston-rod; the other (3 in the figure) takes a screw-cap, by means of which cannulæ of different sizes may be fixed in air-tight

connexion. The needle passes completely through the piston-rod, and, when the syringe is filled, may be withdrawn by unscrewing at 2; the elastic tube, 1, can then be easily attached without any risk of air passing through the cannula.

The advantages of this instrument, as compared with the ordinary subcutaneous syringe used for diagnosis, are: it is stronger and made with a larger tube; the needle-point is at once withdrawn, and the orifice of the instrument cannot get blocked in inserting it; whilst after being used for exhaustion, it may be employed for the injection of anti-septic or other fluids if required. As compared with a larger aspirator, the advantages it possesses appear to be, that the risk of admitting air is considerably diminished, whilst the glass cylinder affords means of observing the flow of fluid close to its point of exit; also that a smaller cannula may be used than can be employed with a larger instrument. It is important, in using it, to see that all the fittings are in working order, and screwed tight.

DR. HAMERTON, resident medical officer of the Lambeth Infirmary, was presented with a handsome testimonial, on the occasion of his leaving, by the officers and others connected with the institution; it consisted of a microscope by Baker, a pocket case of instruments, a gold pencil-case, and a diamond breast-pin. Great regret was expressed by all at his leaving, he having held the office more than five years, and during all that time he was universally respected by his fellow-officers and loved by his patients.

BUTTERINE.—In a Dublin police-court last week, five traders were fined £2 each for exposing for sale as genuine butter a substance known as "butterine," or oleomargarine. This is the first occasion in Dublin that a prosecution has been instituted for the sale of butterine.

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 4, 1880.

THE chief topic of Professor HUMPHRY'S Presidential Address at the recent meeting of the British Medical Association at Cambridge is especially deserving of notice at this time—the approach of a fresh medical session. For many years Professor HUMPHRY has devoted himself to the task of reviving the medical school at Cambridge, and in his address he discussed the subject at great length. He first showed that it was not the original intention of the founders and the first legislators of the University to exclude medicine from the studies at Cambridge. In the earliest College statutes permission or direction is given to some of the members to pursue the study of Medicine, and in the scheme for the University, which was in the main based upon that of the University of Paris, the Faculty of Medicine was placed on an equal footing with those of Theology and Law, and the provisions for teaching and graduating in the three faculties were identical. So, also, in the professorial foundations of HENRY VIII., by which the professorial system was made to supersede the method of teaching by regents, bachelors, and doctors, Medicine shared in common with the other faculties. How have these intentions to establish an actual medical faculty been foiled? The answer is neither direct nor easy, but may be found, says Dr. HUMPHRY, if at all, by a careful study of the history of the past. Some of the causes of failure are peculiar to Cambridge, and some appertain to rival English or continental cities and schools.

After a rapid survey of the history of medicine in Europe from the thirteenth to the seventeenth century, Professor HUMPHRY proceeded to consider in detail some of the circumstances that had militated against the existence of Cambridge as a medical school. The fame and reputation of many of the continental anatomical and medical schools, such as Salerno, Bologna, Paris, and Padua, attracted the best of the English youth, and when they returned to their native country Cambridge did not offer sufficient pecuniary or courtly attractions even for its own *alumni*. HARVEY, for instance, when he returned from Italy, settled in London; and CAIUS first practised in Shrewsbury, and then in Norwich. Even GLISSON, the Regius Professor of Physic in the University of Cambridge from 1637 to 1677, was a resident in London.

Another cause of Cambridge's failure was the ascendancy which the metropolis had gained by the foundation of the College of Physicians. In 1518 the learned LINACRE obtained from HENRY VIII. letters patent to found the College, with the privilege of licensing practitioners throughout the country. Lectures were delivered at the College, and London thus became the chief centre of medical teaching as well as of the licensing of medical practitioners. Thenceforth the metropolitan influence grew apace. Teachers, practitioners, and students were attracted in large numbers,

and the vast population afforded plenty of scope and material for the study of clinical medicine.

Another drawback was the religious restrictions imposed by the University. These restrictions, says Professor HUMPHRY, “wellnigh divested the University of the character of a national institution, and of its claim to public sympathy and regard.”

These defects have, however, at length been removed, and an opportunity is now afforded to Cambridge of taking a distinct place as a centre for teaching the preliminary subjects of medical study, such as natural philosophy, botany, chemistry, anatomy, and physiology. It is, perhaps, not possible, and it is scarcely desirable, to attempt to make of Cambridge a school of practical medicine and surgery; the material is lacking. Medicine, surgery, and pathology can only be adequately studied in the centres of large communities, but the pursuit of chemistry, anatomy, and physiology does not need the same extraneous conditions. Cambridge may very properly take the initiative in alluring would-be medical students to a higher grade of preliminary education, and as the general preliminary education improves the *status* of the medical student will rise in a corresponding degree. It will then not suffice to have the sciences of chemistry, anatomy, and physiology taught by junior medical practitioners, whose chief ambition is to gain a large medical and surgical practice in a big city. Medicine and surgery proper must, of necessity, be taught by trained and experienced practitioners; but chemistry, anatomy, and physiology are best and most worthily taught by skilled professors free from the distracting anxieties of practice. In this way Cambridge is capable of doing a service to the cause of medical education. Its University already possesses, or may easily acquire, the facilities for teaching these important preliminary medical subjects. To the metropolis and other populous districts must be always entrusted the task of furnishing the *matériel* and *personnel* of the strictly medical education.

THERE have been few subjects in pathology more debated than diphtheria, and the special lesion which characterises it—from which indeed it takes its name; and few about which so much needless confusion and mystery have clung. We may now fairly assume that the vexed question of identity between this disease and that styled “membranous croup” has been set at rest, and it is not intended here to raise it again. At any rate, it has been shown conclusively on all sides that there is no anatomical difference in the two diseases, but only a topographical difference as to the seat of the exudation; and similarly, one by one, all etiological, clinical, and other distinctions have faded before the exhaustive analysis of modern inquiry. Still, however, pathologists have differed much upon the subject of the nature of the false membrane in diphtheria, and it is only one instance out of many in pathological histology which show how various may be the interpretations put upon microscopical appearances. The reason for divergence of opinion is not a simple one. It depends, in one instance, upon the different stages at which the exuded product has been observed; in another, upon the different seat at which it has been formed; and sufficient account has not been taken of such essential points as these, whilst too much stress has

been laid upon other and more accidental features. The sad confusion which resulted from the introduction of the terms "croupous" and "diphtheritic," as general pathological phrases, indicative of various forms of inflammation of mucous membranes, with which the German school is to be credited, has done much to complicate the plain facts of the case; and the non-recognition of the fact that the effects of local irritation of a simple kind lead to changes on mucous membranes identical with those produced by the specific irritation of the diphtheritic poison is yet another element which still obscures the subject. A remarkably lucid exposition based upon carefully conducted study of this phase of the question by M. LEOIR, in the current number of the *Archives de Physiologie*, seems to us to be worthy of attention. Although this observer arrives at conclusions differing in some points from those of others, yet he has succeeded well in harmonising many discordant views, and has placed the matter in so clear a light that we think it well to briefly follow him in the course of his reasoning.

M. LEOIR commences by a brief historical summary of the views held upon the nature of the diphtheritic false membrane, and he shows how, from having held the opinion that this is purely a fibrinous exudation, pathologists have come round to view it as one of purely epithelial transformation, the first to enunciate this view being WAGNER in 1866. The truth indeed lies between these two schools, and the way at which this has been arrived has been by experiment. Many observers have hitherto tried to establish the identity between the membranous exudations following the application of irritants to mucous membranes and the specific membranous formations, but have been subjected to much hostile criticism, and have failed to carry conviction. LEOIR has followed the same course, producing the exudations on the fauces and pharynx in dogs, rabbits, and guinea-pigs, chiefly by means of ammonia, and observing the changes produced both by the naked eye and by microscopical examination at intervals varying from fifteen minutes to two or more days after the exposure to the caustic. He has thus been able to trace all stages of evolution of the false membrane. At first the change is simply denoted by redness of the affected patch, which sets in almost immediately after the application. But already the superficial cells of the stratified epithelium exhibit notable changes. A clear space appears around their nuclei; the cells are enlarged, but remain connected, whilst in the deeper strata there is evidence of their proliferation, and the vessels of the submucosa are gorged with leucocytes. About an hour after the application the patch has assumed a semi-transparent opalescent appearance; the perinuclear clear spaces have enlarged, the cell-protoplasm has become fibrillated and of a glistening character, whilst the nuclei remain in parts unchanged, in other parts increased in number but not in character. Thus in this stage the upper layers of what is now a distinct false membrane presents a reticulate appearance, wholly due to changes in the epithelial cells themselves; but in a very short time—five to eight hours—this primary reticulum begins to disintegrate, leucocytes and a fibrinous exudation penetrate the meshwork, until there is formed a thick white opaque membrane, that with which we are most familiar in diphtheria. In this third stage of its evolution the membrane can be resolved into two distinct parts—a *superficial*, com-

posed of fibrinous filaments entangling pus-cells, degenerate epithelial cells, and fragments of the primary reticulum, which still persists in a modified form in the *deeper* layer. In the fourth stage the membrane has assumed a yellowish-grey colour, the epithelial reticulum is almost entirely broken up and replaced by the exuded inflammatory material; and the final stage is that of disintegration of the false membrane, which assumes a pulpy consistency and yellowish colour. If the inflammation has been very intense, the vessels in the submucous tissue are compressed, and necrotic processes of a more or less deep extent take place.

Now, on comparing these changes with those which take place in pharyngeal diphtheria, a perfect similarity is observed between them. As may be imagined, M. LEOIR has had no opportunity of studying the earliest stage of the membrane in this disease, but he was enabled in two cases to meet with areas of exudation in the second or "opalescent" stage, and he found there the reticulum formed from altered cells, the nuclear proliferation, and the commencing invasion of the reticulum by fibrin and leucocytes, just as in his experimental cases; groups of micrococci being found in addition. And so, indeed, with the later and better known stages of the diphtheritic membranous formation; a close identity was found between it and that produced artificially upon the pharynx, fauces, epiglottis, and vocal cords. In the non-stratified epithelium of the larynx and lower air-passages there is no scope for the formation of the epithelial reticulum, and the false membrane is then almost entirely composed of leucocytes and fibrin, a distinction which sufficiently accounts for the well-known difference in the degree of adhesion to the subjacent mucous membrane in this site as compared with the pharynx. The fact that in diphtheria the membrane will re-form after being detached, whereas it does not in the case of simple irritation, is explained by the persistence of the cause of irritation—the specific poison—in the former case, and its absence in the other; and probably also from the blood-plasma being altered in diphtheria, and able more readily to traverse the coats of the vessels. Thus a diphtheritic false membrane is composed not of material simply exuded from the blood alone, nor of alterations in epithelium alone, but both the blood and the epithelial tissues have an important share in its production, the epithelial elements taking a far larger share in the regions where they are normally stratified than where they exist only as a simple layer; and in the former regions it can be shown how (except in a few rare instances, where the inflammatory exudation seems to pass through the epithelial strata almost *ab initio*) the false membrane is primarily of purely epithelial origin, how it becomes more and more mingled with products of exudation, which finally almost wholly compose it. The suggestion, too, is thrown out that cases of death from asphyxia in children, which may occur in the very early stages of the disease, do so by the glottis becoming occluded by the mere preliminary epithelial swelling in addition to the submucous hyperæmia, before the process has reached the stage of actual membrane-formation.

Whilst, moreover, no anatomical basis of distinction exists between diphtheria and croup, neither can any difference be established between the pseudo-membranous products fol-

lowing experimental irritation and those due to the poison of diphtheria. Nay, more than this. M. LELOIR declares that the same anatomical identity underlies all membranous inflammations of the mucous membrane, whether this be in "herpetic angina," in "pellicular" tonsillitis, mucous patches, chancres, &c. And if this be true, we have here only another illustration of like effects following a multiplicity of causes. It is surely far better to interpret facts in this light than to seek in the mere effects of disease for the differences which lie deeper in the organism—viz., the nature and mode of evolution of the so-called "irritant" (in its widest sense) that is at the root of the manifestations. The concluding paragraphs of this paper are taken up with a comparison between these processes and those of pustular eruptions on the skin, but space forbids our entering on the interesting and suggestive inquiries there opened.

ONE of the great therapeutical problems, if not the greatest of such problems before the profession in our time, is the treatment of chronic disease, and of those constitutional faults which underlie chronic disease. If the general practitioner will take his list of patients and write down in a corresponding list the names of each of their diseases, he will be surprised to find what a large proportion of his work has reference to disease that is not acute, and to ailments rather than disease. This impression is got from practice only. In a hospital the medical student sees a severe class of cases, medical or surgical, representing accidents and emergencies and exceptions, rather than the ordinary "ills that flesh is heir to." But he will not have been long in practice before he finds out how different is the set of facts and failings with which he now comes to deal, and how much his peace and satisfaction as a practitioner depend on the intelligence with which he can formulate a judgment with regard to them. He will find his nosological list will not run so much in the heroic style, such as pneumonia, fevers, cerebritis, and peritonitis. It will take less acute forms—as dyspepsia, phthisis, albuminuria, lithiasis, constipation, hæmorrhoids, hæmaturia, epilepsy, diarrhœa, shock, diabetes, cardiac faults, cancer, gout, &c. An acute case or two no doubt give a practitioner much trouble and anxiety for a few days, but such cases are soon over, and the general principles upon which they are to be treated are now pretty well matters of agreement. But with chronic derangements it is otherwise, and unless their significance be quickly and intelligently apprehended the patient drifts into disease, and often into dissatisfaction either with the medical art itself or with the practitioner who in the particular instance represents it. In the latter case he appeals to another practitioner, who brings the disease under definition, and perhaps detects its relation to a cause—a diathesis, or a habit, or a calling. He immediately figures as a superior practitioner, and invidious comparisons are instituted between one physician and another, when with a little more care and thought no occasion need have been given for such comparisons.

We urge the importance of attention to chronic forms of disease from a conviction that it will yield satisfactory results both in a scientific and a practical respect. The drift of our contention may be thus expressed: first, that much of the disease that shortens and embitters life,

where not altogether functional, is chronic—degeneration rather than disease; secondly, that there is reason to believe that the rate of such degenerative processes admits of being quickened or retarded; thirdly, that the indefinite retardation of a degenerative process is practically the extension of life to its natural limits, and the next best thing to a complete cure; that this retardation has come to be a prime function of scientific and practical medicine. We have not space for the elaborate discussion of these several propositions, but they are important with reference especially, be it noted, to the element of *time*, which, as the late Dr. STOKES used to say, constituted so important a factor in disease. Cases are recorded in which even cancer has extended over a period of twenty years or thereabouts. The question upon which light is needed is—Why did the cancerous process in these cases occupy so long a time? What was the condition of the patient, of his temperament, or circumstances, or diathesis, or of his medical treatment, which may be held to have exercised a retarding effect upon an intensely morbid degeneration? Surely if cancer can be extended over twenty years, the time may come when it may be extended over thirty, and practically cease to be a cause of premature death. And of course, if a case of cancer can be so protracted, it is still more reasonable to hope that less intense and virulent degenerations—such as tubercle, or fibrosis, or atheroma—may be so extended. What we urge is that the accomplishment of this extension is not only a part of the science and practice of medicine, but is a most urgent and withal hopeful part of medical work.

Chronic disease and slow changes are too apt to be left to drift, or regarded both by the patient and the practitioner as matters for domestic treatment. Can anything be more unreasonable? We are persuaded that the growth of general intelligence and education will convince the public that, apart from their acute illnesses, the confirmation of health and the strengthening of weak points in the physical system are to be looked for from ever-advancing physiology and medicine. We do not think that this great service of medicine is likely to be accomplished mainly by individual remedies, or by mysterious specifics. Medicines may contribute most importantly to it; but undoubtedly it will be done by Medicine rather than by medicines—by an intelligent use of all those means whereby glands and bloodvessels are preserved in their integrity and blood in its purity, and by bringing life to a close accordance with the laws of health and hygiene. Of late the interest of physicians has been largely devoted to pyrexial disease, to complaints attended by high temperature, acute phenomena, and urgent danger, and this with great advantage. Surely so, when one physician alone has been able to record 120 cases of uncomplicated pneumonia without a death. But meantime slow processes of disease are regarded with little more than pathological interest, whereas, if we be right in our views, they promise a field of hopeful and creditable work for the physician.

THE death has been announced of Professor Buhl, the value of whose researches into the histology of tubercle especially has been universally recognised by pathologists.

Annotations.

"No quid nimis."

THE METROPOLITAN HOSPITAL SATURDAY.

WE are very glad to see that the promoters of the Hospital Saturday movement in London are hopeful of a greater success than in previous years. This is a most modest expectation, and we devoutly hope it will not be disappointed. The fact is—and it ought to be very plainly stated—that the Hospital Saturday collection hitherto has been a thoroughly inadequate business. As the annual offering of the working-men of London to hospitals, from which they and their families derive enormous and almost exclusive benefits, whose doors are always open to them night and day, the five or six thousand pounds raised by the wage-earning class in the whole year are simply discreditable. We do not mean to blame the working-men themselves entirely for this, nor do we wish to blame anybody; but somebody must be at fault—either the working classes themselves or the Board of Delegates—for not devising an organisation or a scheme whereby more than about five thousand pounds can be extracted from them for this great cause. We are persuaded that such a sum does not in any way represent either their gratitude or their judgment in the matter. A collection on one given day seems to be an imperfect way of reaching them. They want the object brought home to them more forcibly and more directly, and they want to be asked for a repeated and even a systematic contribution. It is ridiculous to think that the working-classes of London, who are capable of so much organisation for political and economical purposes, are doing either themselves or the hospitals justice by such collections as have as yet been realised. One glass of beer a day less for a week would make a splendid improvement. The hospitals are very needy; some of them have to close many of their beds. It is a time for a great effort, and even for some personal sacrifice. The Hospital Sunday Fund has this year exceeded its last year's subscription by five thousand pounds. We shall be disappointed if the Hospital Saturday Fund does not do likewise.

THE EDUCATIONAL VALUE OF MUSEUMS.

DR. GUNTHER'S address, delivered before the Biological Section of the British Association for the Advancement of Science, will have the effect of calling the attention of the public at large to the high value set upon museums as a means of instruction even by those who are our pioneers in matters of science and art. A saying that has become trite is almost of necessity true also; and scarcely a day passes but each of us has an opportunity of recognising that

"Segnius irritant animos demissa per aures
Quam quæ sunt oculis subjecta fidelibus."

The collection of modern works of art, quasi-technological as it is, which was established by the late Prince Consort at South Kensington, and which took its origin in the Exhibition of 1851, is the most striking example of the solid value which a museum may have for a nation at large. It is not too much to say that in the thirty years which have elapsed since the first Exhibition we, as a nation, have gone from near the bottom to very near the top of the class in matters of domestic art; and no one will doubt that this result is mainly attributable to the collections at South Kensington, and to the science and art classes established, as it were, for the purpose of teaching how excellence, such as is manifest in the articles exhibited in the museum, is alone attainable. We have conclusively proved that "taste," a faculty which our fathers believed to be the exclusive property of the French, is more a matter of education than a question of in-born national genius.

It is to be hoped that the Biological Museum at South Kensington, now about to commence its career, will bear fruit as abundantly as has the neighbouring Museum of "Science and Art." As far as the museum itself is concerned there is every prospect that it will approach perfection. Miles of shelves, plenty of light, hundreds of thousands of specimens, and men who comprehend the science of arrangement and the art of display, are the factors necessary for the formation of a museum, and all these factors have converged at the Biological Museum of South Kensington. The central hall of the new building is to be devoted to an Index Museum, wherein the student may obtain a comprehensive bird's-eye view, as it were, of the domain of Biology before commencing his more detailed explorations in that particular branch which may most interest him. This should be an essential feature in every museum, and in a museum devoted to so wide a subject as Biology it is indispensable. It is to be hoped also that no parsimony will be shown in the matter of the library, which Dr. Günther rightly insists is a necessity for the new museum. A museum without a library is an absurdity, and it is almost inconceivable that so grand a building, reared at so vast an expense, should not contain an element so absolutely requisite for its utility. This omission will cost the nation an addition of about £100,000, and the library, when established, will probably be in an out-of-the-way corner, instead of in the most accessible spot possible. We should like to know who it is that is really responsible for this blunder, and it would be interesting to be informed of the history of the new museum, and what kind and what amount of counsel was taken with the scientific advisers (if there be any) of the Treasury before the architect was instructed to set to work at his plans. Some years ago a great railway company built at a cost of £80,000 a magnificent new station in a large provincial town, and it was not till the foundations were dug that it was discovered that no space had been allotted for a booking-office, and this omission seems to us to be scarcely less glaring than the omission of the library from the Biological Museum at South Kensington. A library is the very heart of such an establishment, and without one the new museum can be nothing but a veritable valley of dry bones. It is to be hoped also that demonstrations and lectures will be given in the galleries of the new educational establishment, and that, like its sister-museum, it will be instrumental in furnishing a stimulus to biological studies which will be felt throughout the length and breadth of the country and will pervade all classes. The Museum of Science and Art has made us the rivals, if not the superiors, of the French in matters of art. We hope that the Biological Museum will do something to bring us alongside our German brethren in matters of science.

DERMATOLOGY IN AMERICA.

IN our recent comments on the death of the Baron von Hebra, we noticed the marked influence he exerted in encouraging in America the study of the branch of medicine which he made his special field; and a recent notice of the fourth annual meeting of the American Dermatological Association, and the receipt of the Transactions of the third annual meeting (edited by Dr. R. W. Taylor), induce us to direct attention to the erudite and well-written address of last year's President, and to the character of the work in dermatology emanating at present from America. Professor Dubring of Philadelphia took for the subject of his address the "Rise of American Dermatology," and traced in a most interesting way the progress of the study of this subject from the time when it was "an obscure and neglected branch of medicine" until the present period. Up to 1836, when the establishment of a special Infirmary for Diseases of the Skin in New York and a delivery of a

course of lectures marked the increasing interest in the subject, notwithstanding the appearance of translations of the works of Willan, Bateman, Cazenave and Schedel, and occasional scattered meritorious memoirs, dermatology was in an utterly neglected state. From this time, however, American students flocked to the world-renowned Hôpital St. Louis, which for some years impressed the stamp of its teaching on their papers. There was an increasing demand for translations of the best European works, and from 1853 special clinics at the different dispensaries and hospitals were established. It was at this time that Hebra's reputation and the growing School of Dermatology at Vienna began to attract the crowds of American students, who, without neglecting the importance of the vast material accessible at Paris, now spent most of their time at the former city. On their return to the New World, stimulated by Hebra's example, imbued with his spirit, and fortified by his teaching and their devotion to the subject, these physicians found lectureships and special clinics gradually constituted for them at almost all the first-rate universities, hospitals, and dispensaries where they could pursue their work, so that at the present time America can look with pride at the numerous band of workers who are contributing year by year papers of first-rate importance on Dermatology, and advancing its studies in a thoroughly scientific spirit. We must especially congratulate our American brethren on the establishment of a first-class journal devoted to dermatology, on their complete union, and the harmony with which they work together, as seen in the foundation of their association and the meetings of the New York Dermatological Society, as also on the recognition of their position by the profession in America as earnest and thorough workers. All this reminds us of the need for examination of the state of things at home, which certainly compares unfavourably with that abroad; for, notwithstanding the important works of Willan, Bateman, Plumbe, Thomson, Wilson, and others, and the recent earnest teaching of Tilbury Fox, the vast material which Great Britain and her dependencies affords for the study of skin diseases is not well utilised; and there is no union for the furtherance of work, as seen in America, or as exemplified in the newly-constituted society, for fostering the study of diseases of the eye in this country. We hope the day is not far distant when in the land of Willan may be seen an earnest band of workers devoting themselves with one accord to the study of this branch of medicine.

STATION HOSPITALS IN INDIA.

THE Government of India have for some time past had under their consideration the advisability of establishing General Station Hospitals for their troops, British and Native, instead of the present Regimental ones; and, under instruction from Government, the Commander-in-Chief has recently issued orders authorising the Surgeon-General of H.M. British Forces in India to introduce the Station Hospital system at certain garrisons in Bengal. It is ordered that the existing hospital and other buildings are invariably to be made use of, the present empty condition of the Indian Exchequer forbidding any present outlay for new works. We cannot but express our satisfaction at this contemplated change in the organisation of our military hospitals in India. Whatever may be the divergence of opinion amongst military men as to the relative merits of the Regimental or the Station Hospital systems, there can be no doubt that as the latter has now for several years been successfully worked at home, and in all parts of the globe except India, that country should be brought into unison, so far as climate and general surroundings permit, with the hospital arrangements that are ordered for the Army generally. The introduction of the Station Hospital system will

effect a considerable saving in medical establishments generally, not only in the cadre of the medical officers detailed for duty in India, but in medical subordinates, hospital servants and attendants, surgical instruments, medical stores, clothing and equipment. It is patent that the aggregation of the sick into one or two buildings, instead of being spread out into the numerous small units of Regimental hospitals, must conduce to a large financial economy; and if the details of organisation are carefully and judiciously worked out by the responsible head of the Medical Service in India, there can be no reason why the Indian military hospitals should not, both for the comfort and care of the sick, be as successful as are our own in England. In Afghanistan General Field Hospitals have been adopted from the commencement of the campaign, and with signal benefit; so that the system, tried in time of war, and with all the disadvantages of such a climate and country as Afghanistan, should readily prove its superiority when introduced under more favourable conditions.

OIL OF EUCALYPTUS.

In the *Deutsche Medicinische Wochenschrift*, No. 30, Dr. Siegen of Deutz narrates some of the results he has obtained from the use of the oil of *Eucalyptus globulus* in antiseptic surgery. He was induced to experiment with it at the suggestion of Professor Binz, and since 1872 has carried on his investigations of its antiseptic properties. He prepares the solution of the oil by dissolving three grammes in fifteen grammes of alcohol, and diluting with 150 grammes of water. In this solution he soaks ordinary gauze. This dressing is applied in the wet state, covered with the usual gutta-percha tissue, and the whole kept in position by means of gauze bandages. Thus prepared, the eucalyptus gauze does not appear to irritate or produce eczema upon even sensitive skin, and is perfectly antiseptic.

In one case of a child with caseous glands of the neck Dr. Siegen operated—first dipping the instruments in a 2 per cent. solution of the oil and washing the surfaces with the same—by scooping out the contents, draining, and applying a wet eucalyptus dressing as above described. Although the spray was not used in this case, the discharges which had penetrated the gauze were quite sweet upon the third day. The slight amount of pus remained odourless, and on the eighth day the cavities had contracted and healed. In a second case, of a child with right genu valgum, he removed a wedge-shaped portion of the tibia, and after fracture of the fibula and proper adjustment of the bone, dressed with eucalyptus gauze, using the thymol spray. The bone wound healed forthwith, and on the tenth day after the operation only a superficial strip of granulations remained.

In a child with purulent inflammation of the elbow-joint and fistulous openings, Dr. Siegen performed resection of the joint under the thymol spray, and after washing out the wound with an 8 per cent. solution of chloride of zinc, dressed with thymol. The discharges from the wound remained, however, still offensive and profuse, whereupon he changed to eucalyptus dressings, having in the first place washed the surfaces with a 1 per cent. solution of permanganate of potash. After the first dressing the secretion of offensive pus ceased, and the wound rapidly healed.

His fourth case reported was an abscess of the knee, which was similarly treated, and with equally favourable results.

Dr. Siegen's experience has taught him that a 5 per cent. solution of oil of eucalyptus may be employed without any drawbacks. Dressings prepared with this solution may be left undisturbed for four or five days, whilst the 2 per cent. solution dressings remain aseptic for three days.

Dr. Siegen's researches confirm those of Schulz, published in the *Centralblatt f. Chirurgie*, 1880, No. 4, on the use of oil of eucalyptus in antiseptic surgery.

MEDICAL EDUCATION IN THE UNITED STATES.

It is very gratifying to see in the United States indications of dissatisfaction with the low and lax requirements of many of the schools, which in number exceed anything we have to complain of. Every State has several medical schools and boards. The period of education is short, and the examinations are of most various degrees of efficiency; there is not, as with us, any uniform requirement that the student, before commencing medical studies, shall have passed an examination in preliminary education. But many schools lately have made it a condition of admission that entrants must pass such an examination, and they deserve great praise for making such a stand. This step may temporarily reduce the number of their students, but the permanent effect must be advantageous. It would be exceedingly desirable to have published annually a list of those schools which require a preliminary education, and those which do not. Amongst those which do we may mention Bellevue College, New York, the Harvard University, and the Michigan Medical College. There is a disposition not only to secure that entrants into the profession shall have the necessary mental qualifications, but also to extend the period of medical study, which in many of the schools is very short. We would impress on the friends of sound medical education in the States the urgent necessity of reducing the number of competing schools and boards. If this cannot be done, the only other remedy of a great evil will be the creation of an Association of colleges which make medical education and examination a serious business, and from which all loosely conducted institutions should be excluded. There is already an association with this object, but we should be glad to know to what extent it has succeeded.

FETAL ENDOCARDITIS.

THE recognition of fetal endocarditis during intra-uterine life is a diagnostic achievement worthy of note. A girl aged seventeen was admitted into Professor Peter's ward at La Pitié near the end of her pregnancy. An active foetus could be felt in the uterus. The double sound of the fetal head could be heard in the usual situation, but instead of the customary *tic-tac* the first sound was replaced by a blowing murmur, almost immediately succeeded by a sharp sound like the normal second sound, and this was followed by a brief silence. The series was repeated about 130 times a minute. At first the interne, M. H. Barth (who records the case in *La France Médicale*), thought that the murmur was that described by Naegele as due to the compression of the umbilical cord, but its precise limitation to the area in which alone the sounds of the fetal heart were heard, and the absence of any uterine contraction which could cause the compression of the cord, convinced him that the sound must be due to a lesion of one of the cardiac orifices. The murmur was again heard next day, when the labour was actually commencing. The child was born dead, having apparently died during the last period of labour. The child was well-formed, and the organs were healthy with the exception of the heart, which was enormously hypertrophied, and seemed alone almost to fill the thoracic cavity. It was nearly globular in form, the right half being much larger than the left. The valves on the left side of the heart, and those of the pulmonary artery, were healthy, but the tricuspid valve was the seat of a "plastic vegetative endocarditis," the free edge being thickened, covered with projections, and its upper surface being uneven. The chordæ tendinæ were shortened and thickened, maintaining the valves in contiguity to the walls of the ventricle, so that it was impossible for them to fulfil their normal function. The right ventricle was dilated and greatly hypertrophied.

The case has a practical lesson. The labour offered no diffi-

culties to which the death of the child could be ascribed, and it was doubtless due to the cardiac lesion. In such a case, in which fetal endocarditis has been diagnosed, the acceleration of the labour by all possible means is desirable, to afford the child a better chance of life. The mother, it may be noted, had never suffered from rheumatism, and presented, in her history, nothing to which the fetal condition could be ascribed. Whether she had suffered from syphilis is not noted.

FEEDING TO LIVE, AND LIVING TO FEED.

THE chemistry and, what may be called, the "physiology" of food and feeding compose a subject which is, of course, trite to the profession, and has been made almost tedious to the public. Nevertheless, we venture to offer one or two remarks for general consideration. The points to which they relate have possibly been overlooked in the attention given to matters which appear to possess claims of higher importance. First, there is an essential difference between appetite and hunger. Appetite is the result or expression of a number of longings or desires which do not necessarily indicate a systemic need of nourishment. Mere appetite *may* indicate organic need, but, if so, the organ in which the requirement exists is the stomach, and it is quite as likely that the viscus demands the food for its own functional purposes, as to pass it on to the system generally. The notion that appetite is a low degree of hunger, and hunger an intensified form of appetite, does not seem to be borne out by facts. The two desires or longings are different in their nature. Appetite is the craving of the apparatus of taste, and sometimes of the digestive organs; while hunger is the demand of the organism as a whole or of some of its parts for food. Use the words appetite and hunger how we may, there are actually two needs to be expressed, and much mischief arises from confounding them. The one cry for food which we call appetite is an affair of habit or caprice, and may, for a time at least, be stimulated by appealing to the sense of taste, or promoted by certain cordials and stimulants; but, looking at the matter from a physiological point of view, it is difficult to see what we gain by exciting the organs of digestion to take food unless the system is in a condition to receive it. The rational mode of procedure would seem to be to wait the expression of a need arising in the system—in short, to look to hunger rather than appetite as an incentive to the act of feeding, instead of exciting the palate and sense organs to take food when we have no organic reason to suppose that there is an inner need of it. There are certain evil consequences of the civilised mode of feeding by appetite, on the basis of habit, which it may be useful to point out. First, separating appetite from hunger, and developing it as an independent sense or function, there naturally springs up a fashion of life which may be described as "living to feed." The purveyor of food trades on the tastes and cultivated longings of the consumer, and the consideration what to eat and what to drink comes to occupy a place in the self-consciousness which it was probably not intended to fill, and in so far as this is the case man is more animal, and less spiritual and intellectual, than he ought to be; although it may be conceded that the refined taste of the cultivated nature is less offensive than the simple voracity of the savage. There are some who contend that man is the gainer by the development of his appetite. If this be so, the gain is a good not unmixed with evil. Another drawback is, that by severing appetite from hunger we lose the indication of quantity which nature gives with her orders for food. The man who eats a regulated number of meals daily with a duly stimulated and organised habit, probably eats much more in the twenty-four hours than his system requires, or the organism as a whole is constituted to deal with. The organs of digestion aid

assimilation are overworked, and hence, doubtless, many of the most troublesome diseases. A glance at any table showing the length of time which the commonest articles of food take to digest will show that the fashionable stomach can scarcely ever be empty. Again, so much solid food being taken, or, which amounts to the same thing, small quantities of food being deposited in the stomach so frequently, an artificial system of "flushing" becomes necessary, and a considerable amount of fluid is "required," not because the system needs *water*—which is the only liquid it actually appropriates, let us dose it with what we may,—but because the apparatus of digestion cannot perform the task imposed upon it except by the aid of fluid to moisten its surface and free the mechanical reservoirs from the *débris* of food with which they are encrusted. Moreover, this artificial appetite tends to the amplification of bulk in respect to food. The quantity of each description of food taken is diminished, because the meal is subdivided to suit the taste; but the total bulk is increased. We do not say the weight of food consumed is greater, but its substance is extended by the multiplication of dishes and sauces, so that the points of contact—the stimulating superficies of the food, so to say—are extended. It should not be forgotten that hunger is the natural expression of organic need; while appetite may be, and generally is, the pampered product of cultivated modes and habits of existence. Appetite in its development tends to living to feed, while with the guide of hunger a man only feeds to live.

A CONSTANT BATH TREATMENT OF FEVER.

DR. REISS, of Berlin, has proposed the employment of the bath in the treatment of typhoid and other febrile diseases, in a somewhat novel form. The antipyretic effect of brief and powerful refrigeration is often transient, and at the height of the disease hourly or half-hourly baths have to be employed. It is proposed, therefore, to employ a continuous but slighter refrigerating agent—namely, to keep the patient constantly in a bath of lukewarm water. A temperature of 88° has been found the most convenient. The use of such baths obviously prevents considerable practical difficulties, which are, however, not insurmountable. The patient should lie in a sheet suspended, hammock-like, within the bath, and when the first inconveniences are over the patients enjoy it, and can be kept in it for a whole day or several days. Dr. Reiss has tried the method in forty-eight cases of typhoid (besides one incompletely treated case). It was used only in pronounced cases, for the most part in the early stage, the bath being commenced at from the third to the twelfth day. The temperature was taken every one or two hours, in either the rectum or axilla. As a rule the bath was continued without intermission for the first twenty-four hours, unless the fall of temperature was too great. After the second day the rule was followed to take the patient from the bath whenever the rectal temperature was below 99·2°, and to reimmerge whenever the temperature rose above 101·5° F. The results are said to be strikingly good. With the exception of some very obstinate cases, the temperature fell quickly in the bath so as to reach the normal in from twelve to twenty-four hours. On removal, the temperature rose rapidly in the earlier stages of the disease, more slowly in the later periods, so that the intervals between successive baths were at first short and afterwards gradually lengthened. In obstinate cases, in which the bath at 88° F. did not reduce the temperature below 102°, transient cooler baths were employed to keep the temperature down.

In forty-two cases available for comparison, the duration of the bath-treatment varied between seven and thirty-eight days, and was, on an average, 18·2 days. Of the forty-eight cases, three died, giving a mortality of 6·2 per cent. In two of these there was pneumonia. The latter fact seems to suggest that this method is not free from the danger of occa-

sionally doing harm, but the influence of the bath on the other symptoms of the disease is said to have been not unfavourable. The pulse remains frequent, contrasting with the depressed temperature, but it often improves in quality. The most favourable effect is produced upon the cerebral symptoms, somnolence or delirium rapidly ceasing. Any severe pulmonary or intestinal symptoms were absent in most of the cases.

ACTION FOR RECOVERY OF SURGICAL CHARGES IN SCOTLAND.

THE *Dundee Courier* of August 25th gives a good account of an action for recovery of charges by Dr. McCallum, of St. Martin's, in the case of a patient who had sprained her wrist. The patient, being impatient, went off to one of those persons who are apt at discovering fractures and dislocations which have no existence. He diagnosed "dislocation," and the patient declined to pay the charges of Dr. McCallum on the ground that he had misunderstood the case and had charged too high. Dr. McCallum showed his respect for his own diagnosis and treatment, as well as his charges, by taking the matter into the Sheriff's Court. By consent of parties the Court remitted the case for report to Dr. Bramwell, of Perth, who made an able statement of it, and entirely confirmed Dr. McCallum's diagnosis and charges. The Sheriff, of course, decreed for the sum claimed with expenses. The procedure is altogether worthy of consideration and imitation. If County Court judges would, with consent of parties, oftener refer to practitioners of standing, and be guided by their decision, much time and money and good feeling would be saved.

CHOLERA IN INDIA.

WE regret to find by our letters from India received by the last mail that cholera has made its appearance in several stations in Bengal and the North-West provinces. In Lucknow the 13th Hussars and Royal Artillery had several fatal cases in the last week in July. At Moradabad the 2nd Queen's have also had a few cases, though of a milder type; while at Allahabad the 2nd Batt. 22nd Regt. has suffered somewhat more severely, losing ten men and an officer (Dr. Noad, whose death is referred to elsewhere) in a few days. In the Punjab, cholera has also appeared at Peshawur, at Tangi in the Peshawur Valley, and at one or two places in the Khyber. We sincerely trust the troops returning to India from Cabul by this route will not again experience such a severe epidemic as was encountered last year, and which decimated some of our finest regiments, notably the 10th Hussars and 4th Battalion Rifle Brigade, whose losses between Jellalabad and Ali Musjid were terribly heavy.

PEROXIDE OF HYDROGEN AS AN ANTISEPTIC.

OUR attention has been drawn to an omission in an article which appeared in our last number on "The Influence of Peroxide of Hydrogen on Fermentation," by which an apparent injustice was unwittingly done to a distinguished English observer. In noticing the recent researches of M. Regnard on this subject the prior investigations of Dr. B. W. Richardson on the antiseptic properties of the peroxide should have been referred to. As early as 1858, we believe, Dr. Richardson called attention to this quality of the gas; and two years ago, in the Cantor Lectures, delivered before the Society of Arts, he dealt very fully with the question of oxygen and peroxide of hydrogen as preventers of putrefaction. A single extract from Lecture IV. of the series will suffice as an example:—"I took a strong bottle with a thick neck, placed in it muscle of beef, and charged it with ordinary oxygen gas. Then I put into the bottle a measured quantity of solution

of peroxide of hydrogen, introduced the fluid in such a way that it did not come into contact with the meat until a cork was inserted into the neck of the bottle and tied down, after the manner of the cork of a soda-water bottle. The bottle was then turned until a portion of the meat came in contact with the solution of peroxide. With that contact there was rapid evolution of oxygen, and a pressure of gas equal to three atmospheres was produced. In this condition small specimens of beef were preserved through the return voyage [to Rio Janeiro and back] and came home in a state of excellent preservation."

THE DEMAND FOR THE APOTHECARIES' LICENCE.

MR. BRADFORD, in the evidence which he intended to have given before the Select Committee of the House of Commons, naturally made a point of the fact that the licence of the Apothecaries' Society is still in much demand. It becomes interesting to know whether the demand is an increasing or a decreasing one. In answer to our request, Mr. Bradford has kindly furnished us with the following data, giving the average number of persons who, in three successive decades, have taken annually the licence of the Society:—

In the decade 1850-1859	295.1
" 1860-1869	291
" 1870-1879	214.9

Making allowance for increase of population, it appears from these figures that the demand for the licence is considerably on the decrease.

THE CANAL BOATS ACT.

MR. GEORGE SMITH, of Coalville, is still dissatisfied with the working of the Canal Boats Act of 1877. In a letter to *The Times* he complains that the measure is in many places little more than a dead letter, though in others it is working satisfactorily. On a visit to one of the midland registration districts a few weeks since, he found the local inspector doing his work well, but outside his city boundaries and within a radius of six miles, twenty-five to thirty boats could be seen unregistered and uninspected, and here overcrowding of both sexes existed as flagrantly as before legislation was attempted. Mr. Smith recommends that the 5s. registration fee be made an annual payment, that the school-inspector be allowed to enter the boats, and the children's education be ensured by the use of a pass-book, similar to the plan proposed to meet the case of gipsy children.

AN earnest attempt is being made by several influential inhabitants of Sydney, New South Wales, to establish a Hospital Sunday movement in that city. The principal medical charity there, the Adelaide Hospital, appears, however, to be a purely Government institution, and on this account the proposal has encountered the opposition of the Anglican bishop and others. The advocates of the scheme have now obtained the active co-operation of the mayor (Mr. E. T. Smith) as chairman and treasurer, and this important accession to their ranks is regarded as an augury of their success.

THE following paragraph appears in the *New York Herald* of the 17th ult.:—"Philadelphia, Pa., Aug. 17th, 1880. John Buchanan, dean of the 'Eclectic Medical College,' who was under heavy bail for his appearance before the United States Court to answer charges of fraudulently issuing medical diplomas, ended his career this morning by drowning."

A DISTINGUISHED service reward of £100 per annum has been conferred upon Sir W. M. Muir, M.D., K.C.B., Director-General of the Army Medical Department.

DR. EDWARD B. SINCLAIR, King's Professor of Midwifery in the Medical School of Trinity College, and Physician to Sir Patrick Dun's Hospital and Maternity, has received the honour of knighthood in recognition of the public service he has rendered by training soldiers' wives as midwives.

WE regret to announce the death from cholera at Allahabad, East Indies, on the 31st of July, of Surgeon Hartley J. Noad, A.M.D. Mr. Noad obtained his commission as a surgeon in the Army in August, 1878, and is the first officer who has fallen a victim to the cholera epidemic this year.

DR. BATEMAN of Norwich and Dr. Hack Tuke of London have been elected Corresponding Members of the Society of Psychiatry of St. Petersburg. Dr. Tuke has also been elected an Honorary Member of the American Association of Hospitals for the Insane.

AT the meeting of the Pharmaceutical Conference at Swansea, on the 25th ult., an address and 500 volumes of books were presented to Professor Attfield.

THE fifty-third annual session of the German Naturalists and Physicians will take place in Dantzic from Sept. 17th to the 24th of the present year.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Kensington.—Among the reports of Metropolitan medical officers of health, Dr. T. Orme Dudfield's annual reports have long held quite a special position. They treat not only of the health and sanitary condition of the particular district, the parish of St. Mary Abbot's, Kensington, over which he exercises sanitary supervision, but of those numerous general questions which concern Kensington in common with the rest of the metropolis. Hence his reports have a much wider interest than that which attaches to the locality to which they primarily refer, and they form singularly instructive commentaries on questions relating to the general sanitary administration of the metropolis. The experience of Kensington is reported not merely in the immediate interest of that important district, but it is made to serve as a text illustrative of yet unsatisfied requirements, or for elucidating difficult questions concerning the public health of that district and the metropolis at large.

Dr. Dudfield's report for 1879 is now before us. We do not propose to follow him in the careful analysis he makes of the vital statistics of his district; neither do we propose to occupy ourselves with his examination of the causes of death during the year. We shall touch only on a few of those questions of more general interest which he takes occasion to discuss in the course of his report.

And, first, with reference to the atmospheric diffusion of small-pox contagion from the Fulham Small-pox Hospital into localities adjacent to the hospital, including places within the parish of Kensington. Dr. Dudfield enters into this question at considerable length, and is enabled to furnish additional detailed evidence from previously unpublished letters of the medical superintendent, Dr. Makuna, to show that the cases of small-pox which occurred in the localities surrounding the hospital had their origin in the ordinary mode of communication of the disease from case to case, the assumption that the hospital was concerned in the dissemination being wholly gratuitous. The patients attacked, it was found, had almost without exception been visiting localities where the disease was prevalent, or had been in direct or indirect communication with persons suffering from the disease. There seems little doubt, more-

over, that had the Metropolitan Asylum Board, or, perhaps, we should say the Local Government Board, taken the least intelligent interest in this question of small-pox, clear histories of the cases of small-pox in the vicinity of the hospital might have been obtained from the beginning, and the mischievous accusation against the hospital stopped at the outset. But, notwithstanding the warning at Hampstead, where a course was followed similar to that pursued at Fulham and the other small-pox hospitals, and where in consequence the Metropolitan Asylum Board has found it impracticable to rebut the evidence as against the hospital, both the Metropolitan Board and the Local Government Board have been and are determined to treat the question as a mere Poor-law question. The latter Board has not recognised a public-health duty in the matter, although the Central Public Authority, and the former Board, encouraged by the Central Board, has treated it on the purely parish basis. "The presumed extension of disease beyond the precincts of the hospital concerns the next parish and not ours"; and to this view of the question the Local Government Board has assented. We see the results of this short-sighted policy in one form in the Hampstead Hospital case; and other and not improbably graver forms will, we fear, follow.

Dr. Dudfield discusses the attempt of the Government to deal with the question of hospital accommodation for infectious disease in the metropolis by Section 15 of the Poor-law Act, 1879, which enables the Metropolitan Asylums Board to contract with vestries and district boards for the admission of patients into their hospitals. The provision has practically failed, and must fail, Dr. Dudfield holds, until pauper and non-pauper patients can be clearly discriminated. Dr. Dudfield is disposed to represent the vestries and district boards in a very virtuous light in the discussion, but his account of the matter reads to us much more like an ingenious evasion by those bodies of an important duty, such as the metropolis has been familiarised with since 1871-72, than action worthy of being attributed to higher considerations. However this may be, this is quite a subordinate matter in view of the relation of the Poor-law authority to hospital administration for sanitary objects. Sanitary authorities have certainly serious grounds for holding aloof from Poor-law administration, and we agree with Dr. Dudfield that until the hospital treatment of infectious diseases is severed from Poor-law administration the question at issue will never be satisfactorily solved.

Dr. Dudfield's observations, tending to show the necessity for legislation to ensure in the metropolis the compulsory disclosure of the occurrence of infectious diseases, deserve careful consideration.

We must pass over several general questions without remark, and we say, in conclusion, that as a description of what is involved in the sanitary administration of a metropolitan district, this report is of the greatest interest.

Sidmouth.—Dr. Pullin's report for 1879 shows a birth-rate of 20·30 per 1000 of the population, and a death-rate of 20·00 per 1000. In plain figures, the births exceeded the deaths only by 2; and the rate of mortality of this beautifully situated place, on the south coast of Devon, with its diminutive population of less than 4000, came perilously near to that of a large town. It is well-known that the sanitary authority of Sidmouth have been so content with the natural advantages of the position of the town, and the high reputation of its medical officer of health, that they long held any serious efforts for maintaining the wholesomeness of the place superfluous. Not long ago, however, they were stimulated to take a somewhat more rational view of their functions and duties by the Local Government Board, acting upon local complaint; but, small as the place and the population are, there is, according to Dr. Pullin's report, a good deal of sanitary work to be done in it before it can offer fully those local conditions of wholesomeness which visitors to health-resorts should desire in their individual interest. With abundant excellent water accessible, it is by no means certain that the occasional visitor may not have to drink water from wells polluted with sewage; and it would appear that 400 of the population—that is to say, one-tenth—are dependent for their water-supply upon "a single hand-well, inconveniently remote from most of them." It is proposed to lay down 1466 yards of sewerage, which being done will secure to the town, Dr. Pullin states, a drainage so complete and efficient that nothing will be left to be desired; but which left undone shows how exceedingly inefficient the sewerage of the town has been and must continue to be until the projected works are completed. More-

over, no precautions appear to be taken to cut off the direct communication of the house drains with the sewers; and, strange to say, the "D" trap is regarded with approval, even by the medical officer of health. The sanitary condition of cottages would appear to be receiving detailed attention, and Dr. Pullin states that closet accommodation, "generally speaking," is "satisfactorily provided." He adds, however, that "the exceptions have been again and again brought to the notice of the [Local] Board, and as their absence continues to prove a serious nuisance to tenants, their immediate erection should be insisted on." Their absence proves also the apathy of the Local Board to the true sanitary interests of the place. Nuisance from piggeries and slaughter-houses has been diminished, but not done away with; and it might be inferred from Dr. Pullin's phraseology that in these matters the Board had to deal with piggeries and slaughter-houses as numerous as the ordinary houses of the town, instead of a few places, nuisance from which ought not to have required three months in dealing with effectually.

REPORTS OF POOR-LAW MEDICAL OFFICERS.

Dr. Alfred Sheen sends us a copy of his annual medical report, 1879-80, to the Cardiff Board of Guardians on the workhouse and schools of the Union. It is somewhat unusual, we believe, for reports of this nature to be printed and issued, but the practice now followed at Cardiff might be usefully copied elsewhere. Dr. Sheen's report gives an interesting account of the movement of patients in the workhouse, and touches upon several matters of interest relating to the medical administration of these institutions. He writes of the Cardiff workhouse as losing much of its original intention as a test of poverty, and becoming to a very large extent an institution for the treatment of sick paupers; and he observes with reference to this state of things, that "it behoves those in authority, in the interests of the sick poor, and so indirectly of the ratepayers, to facilitate the recovery of these sick paupers by every means in their power." The Cardiff guardians are acting upon this view of the subject, as exemplified by the erection of an excellent hospital and the appointment of a staff of paid nurses. Referring to the question of the use of stimulants in workhouses, Dr. Sheen remarks: "The discussion has tended to do good where it has awakened medical officers to a greater sense of their responsibility in this matter; but to attempt to treat many cases we get in a workhouse infirmary without stimulants is, to say the least of it, harsh and unfeeling."

THE SANITARY CONDITION OF WHITEHALL.

Our contemporary the *Builder* has been directing attention to the state of drainage of Whitehall and the district of Westminster generally. Of its own knowledge it speaks ill of the subsidiary drainage of the low-lying parts, and, on the authority of Sir Joseph Bazalgette, it takes except on to the principle on which the main-drainage of the district has been carried out. It holds, in fact, that "a reconsideration of the drainage of Westminster is a matter of primary importance in the behalf of the public health"; and although when a question was asked in the House of Commons on this subject Mr. Adams answered that it was matter which rested with the Metropolitan Board of Works, and not with the Government, we should have thought that the Government had at least sufficient personal interest in it, so far at least as Whitehall was concerned, not to put it lightly aside or to leave it to the good-will and pleasure of the Metropolitan Board of Works without an expression of opinion, if the allegation were correct. Moreover, there was more involved in the question than Mr. Adams admitted. In regard to main-drainage, no doubt he was right in saying that it was a subject in which the Metropolitan Board of Works was concerned; but in regard to subsidiary drainage he was judiciously silent. The subject arose out of the illness of Mr. Gladstone and the rumours that gained prevalence at the beginning of his indisposition that he was suffering from typhoid fever. It was curious to no e how very generally this suspicion was roused simply because the Prime Minister occupied one of the houses in Downing-street. It seemed to be taken for granted that the drainage of the buildings there must necessarily be defective, not because they were old buildings, but because they were under the direction of a Government department. There appears to be much more of sound reason in this argument than is commonly understood. It is believed that the massive pile of buildings forming the new Government

offices is a marvel of bad sanitary arrangement and drainage. It is known that the defects in the office of the Local Government Board have been of the most serious character, and it is to be inferred that they still continue to be so, for it is found necessary to keep the corridors of this portion of the new building charged with carbolic acid to an extent positively sickening to not a few members of deputations who have had the misfortune to visit Mr. Dodson lately. If this be the state of things in the new buildings, what may be inferred of the drainage arrangements of the old, built at a time when sanitary requirements were in vogue of a much cruder kind than ought to be tolerated now? If Westminster, whether old or new, has much of its drainage arrangements carried out in the same fashion as Whitehall and the Government buildings there, the question at issue covers wider ground than the Metropolitan Board of Works can deal with, and is one that in the interest of the Government, the Legislature, and the inhabitants of the district in general, it would be well to submit to public inquiry.

THE METROPOLITAN WATER-SUPPLY.

Colonel Bolton, R.E., the water examiner, in his report on the state of the water delivered by the Metropolitan Water Companies in July, says of that derived from the Thames, that although there were not more than twelve days in which the stream was free from turbidity, the filtration was generally efficient, and the filtered water clear, if not bright. In previous reports Colonel Bolton has discussed briefly the question of a "standard of filtration"; in this report he refers to the desirability of instituting a "standard of quality." He devotes, moreover, a part of his report to the brief consideration of the negligence of householders in the storage of water, and particularly the filthy condition in which cisterns are too commonly kept, especially as observed in the tenemented and cottage class of houses. He alludes to the illustrations of this neglect which may be so abundantly observed from the windows of the trains on many of the lines of railways leaving London. And he directs attention also to the frequency with which the waste-pipes of cisterns are directly connected with sewers, and to the liability to pollution of the water with sewer-air in consequence. These are very old and very scandalous defects, but in the state of sanitary administration in the metropolis we see little hope of their being amended in detail except by the general extension of a "constant" water-service on the one hand, and the adoption of buildings' bye-laws by the local authorities on the other. A very gradual extension of the "constant" service is taking place, and we live in hope that some day even a metropolitan sanitary authority may awake to a reasonable understanding of the magnitude of the health interests involved in the question. It rests chiefly with the local authorities to secure the boon of a constant water-supply for the metropolis, and to get rid of those scandals of domestic storage which too often converts the filtered and deep well-water distributed by the water companies into a filthy, disgusting fluid—disgusting alike to taste and smell.

THE DRAINAGE OF WORKHOUSES.

When last week we had occasion to notice the circular recently issued by the Local Government Board on the drainage of workhouses, we fell into the double error of under-rating the capacity of Boards of Guardians for going wrong, and of over-rating the power of the Local Government Board in setting them right. We learn that the Chester Board of Guardians have within the past two years erected a new workhouse, and that this building is quite a marvel of structural perversity. Hardly had the occupants been installed before the building began to fall to pieces; and this state of things above ground proves to be paralleled by the condition of things below ground. The drainage is, indeed, reported to be in so bad a state that the Local Government Board has had to interfere, using the imperative powers it holds in reserve for wilful guardians. The Chester Board "grumbles" at being victimised in a new building for which it alone can be responsible, and for which it has paid £40,000. It will be interesting to know by what miracle of ingenuity this extraordinary muddle can have been brought about, and the various presumed checks or powers on careless Guardians evaded. We hope some member of Parliament in the course of next session will ask for information and papers on the subject. First, there are the Guardians, then there is the

general inspector of the Local Government Board, that Board itself, and its architect, all of whom must have a hand in the matter before the local architect and contractor can proceed with the building, and yet the result may be as reported. Evidently the outer world of ratepayers has not penetrated much beneath the surface of the mysteries which surround local and central Bumbledom.

REMOVAL OF PATIENTS TO SANITARY HOSPITALS.

Considerable trouble would appear to have been experienced at Chesham, in Bucks, during a recent prevalence of fever, in inducing patients to be removed to the sanitary authority's hospital. Particularly it has been found difficult to persuade parents to have young children removed. We infer from the local journals that much of this difficulty has arisen from the sanitary authority having allowed their hospital, during a period of freedom from infectious disease, to get out of repair, and so to become prejudiced in the eyes of the community. This should be a caution to authorities possessing hospitals. At the best people are not eager to avail themselves of these hospitals, and no needless antipathy should be created against them. These institutions are new to our communities, and the latter have not had time to become acquainted with the advantages to be derived from them. It is surprising, however, in how many instances, where thoughtful care has been used, the objections to entering sanitary hospitals have been overcome. It should never be forgotten in respect to children that Dr. Ashby of Grantham succeeded during a recent epidemic of scarlet fever in prevailing upon parents to make large use of a tent hospital erected by the sanitary authority on his advice.

Dr. Hardwicke recently held an inquest in Coldbath-fields Prison on the death of an individual who had been removed from his house at Fulham in a dying state under an order of the magistrates, and in consequence of proceedings of the sanitary authority against him in that his house was unfit for occupation. The Coroner observed that the case was a very cruel one—an expression of opinion in which the jury concurred.

It is reported that recently considerable alarm was caused in the parish of St. George-in-the-East by the sound of an explosion in the common sewer. It was subsequently ascertained that this had been produced by the sudden closing of a penstock at one of the storm overflow outlets. The concussion of air thus produced was so great as to disturb some of the work at a side entrance of the sewer.

The Local Government Board for Ireland have urged upon the Waterford Board of Guardians the necessity of adopting prompt measures for improving the sanitary condition of Mooncoin before the winter sets in; and have acquainted the guardians that application can be made for a loan for that purpose under the provisions of the Public Health Act, as suggested by the dispensary committee.

A common lodging-house keeper was recently charged at Stratford-on-Avon with having infringed the bye-laws of the urban sanitary authority. His house was licensed for 21 lodgers, but on an inspection was found to contain 50. He pleaded in defence that during the harvest season lodging-houses had to be conducted on "Irish notions."

The Health Committee of Liverpool have recommended that the Town Council should seek the assent of the Local Government Board to a proposal for the erection by the Council of artisans' dwellings, to meet the domiciliary necessities of a large number of poor people who have been dislodged from the foul corner called Nash Grove.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

The increase in the rate of urban mortality last week may again be considered due to the fatality of summer diarrhoea among children. In twenty of the largest English towns, estimated to contain in the middle of this year seven and a half millions of persons, or nearly one-third of the entire population of England and Wales, 5041 births and 3605 deaths were registered last week. The births were 144 below, whereas the deaths exceeded by 330, the average weekly numbers during 1879. The deaths showed an increase of

115 upon the number returned in the preceding week. The annual death-rate per 1000, which in the preceding week declined slightly, rose again last week to 25.1, which was the highest rate recorded during the current quarter. During the past eight weeks of the quarter the death-rate has averaged 22.7 per 1000 in these twenty towns, against 25.4 and 17.8 in the corresponding periods of 1878 and 1879. The lowest death-rates in the twenty towns last week were 16.4 in Bristol, 19.4 in Oldham, 20.9 in Plymouth, 21.0 in Portsmouth, 21.2 in London, and 21.4 in Brighton. The rates in the other towns ranged upwards to 32.9 in Manchester, 33.1 in Salford, 34.5 in Leicester, and 35.0 in Liverpool. The high death-rates in these last-mentioned towns were mainly due to excessive diarrhoea fatality.

The deaths referred to the seven principal zymotic diseases in the twenty towns, which had steadily increased from 406 to 1136 in the eleven preceding weeks, further rose to 1239 last week. These included 958 from diarrhoea, 105 from scarlet fever, 76 from whooping-cough, 49 from different forms of fever, and 32 from measles. The annual death-rate from these seven diseases averaged 8.6 per 1000 in the twenty towns; while it was but 4.6 and 4.9 in Bristol and Brighton, it ranged upwards to 15.7 and 20.9 in Salford and Leicester. Scarlet fever was proportionately most fatal in Sunderland and Norwich. Of the 16 deaths from diphtheria 13 were returned in London. The 32 fatal cases of measles were the lowest number recorded in any week of the present year. Small-pox caused 3 more deaths in London, but not one in any of the nineteen large provincial towns. The number of small-pox patients in the Metropolitan Asylum Hospitals, which had declined from 200 to 135 in the six preceding weeks, further fell to 128 on Saturday last; 26 new cases of small-pox were, however, admitted to these hospitals during the week, against 20 and 30 in the two previous weeks. The Highgate Small-pox Hospital contained 11 patients on Saturday last.

The fatal cases of diarrhoea in the twenty towns, which in the ten preceding weeks had steadily increased from 51 to 364, further rose last week to 958. The annual death-rate from diarrhoea averaged 6.7 per 1000 in the twenty towns; it was equal to 3.8 in London, and to 9.4 in the nineteen large provincial towns. The death-rate from diarrhoea among the twenty towns ranged last week from 2.7 and 3.2 in Oldham and Bristol to 13.0 and 18.1 in Sheffield and Leicester. In the last-mentioned town the diarrhoea rate showed a decline from that of the preceding week.

The deaths referred to diseases of the respiratory organs which had been 152 and 167 in London in the two preceding weeks, declined to 124 last week, and were 14 below the corrected weekly average. Of these 124 deaths 63 were attributed to bronchitis and 40 to pneumonia. The annual death-rate from diseases of this class was equal to 1.8 per 1000 in London, and 3.2 in Liverpool.

HEALTH OF SCOTCH TOWNS.

In eight of the largest Scotch towns, having an estimated population of rather more than a million and a quarter persons, the annual death-rate last week averaged 18.4 per 1000, showing a further decline from the rates, 20.1 and 18.6, in the two preceding weeks; this rate was, moreover, 6.7 below the average rate in the twenty large English towns. The rates in the eight Scotch towns ranged from 13.1 and 15.1 in Greenock and Aberdeen, to 27.3 and 28.4 in Perth and Leith. The fatal cases of the seven principal zymotic diseases in the eight towns were 123, against 122 and 127 in the two preceding weeks; they included 63 from diarrhoea, 17 from whooping-cough, 16 from scarlet fever, 13 from diphtheria, 12 from fever, 2 from measles, and not one from small-pox. The annual death-rate from these seven diseases averaged 5.0 per 1000 in the eight towns, against 8.6 in the large English towns. The excess of the zymotic death-rate in the English towns was due to the greater fatality of infantile diarrhoea. The zymotic death-rate in the Scotch towns ranged from 1.3 and 1.9 in Greenock and Perth, to 6.4 and 10.7 in Paisley and Leith; the excess in Paisley was due to diarrhoea, and in Leith to scarlet fever and diarrhoea. The fatal cases of diarrhoea in the eight towns, which had been 51 and 65 in the two preceding weeks, declined to 63 last week; the annual death-rate from this disease did not average more than 2.5 per 1000 in these eight towns, while in the large English towns the rate was equal to 6.7. The highest rates from diarrhoea in the Scotch towns were recorded in

Aberdeen and Leith. The 17 deaths from whooping-cough (a decline from the average of recent weeks) included 7 in Glasgow and 3 in Dundee. Six of the fatal cases of scarlet fever were returned in Glasgow, 5 in Leith, and 4 in Edinburgh. Eight deaths from diphtheria were registered in Glasgow, and a fatal case of measles was recorded in Glasgow and Aberdeen. The deaths referred to fever, which were 17 and 7 in the two previous weeks, rose to 12 last week, of which 11 were returned in Glasgow. The deaths attributed to acute diseases of the lungs (bronchitis, pneumonia, and pleurisy) were 55 in the eight Scotch towns last week, against 70 and 39 in the two preceding weeks; the annual death-rate from these diseases was equal to 2.2 per 1000, against 1.8 in London. The causes of 110, or 24 per cent. of the 458 deaths registered in the Scotch towns last week were uncertified; in the English towns the proportion of uncertified causes of death scarcely exceeded 2 per cent.

HEALTH OF DUBLIN.

The rate of mortality in Dublin last week corresponded with that of the previous week, which was so high as 37.8 per 1000. During the past eight weeks of the present quarter the death-rate in the city has averaged 33.3 per 1000, against 22.0 in London and 17.8 in Edinburgh. The 228 deaths in Dublin included 63, or no less than 28 per cent., which were referred to the seven principal zymotic diseases, showing an increase of 7 on the number returned in the preceding week; 9 resulted from measles, 5 from scarlet fever, 8 from whooping-cough, 5 from different forms of fever, and no less than 36 from diarrhoea. The annual death-rate from these seven diseases was equal to 10.5 in Dublin last week, against 5.6 in London and 2.5 in Edinburgh. No death from small-pox was registered in Dublin last week, and it may be noted that since the first week of February, 1878, the city has not been free from a fatal case of this disease. Measles and whooping-cough showed an increase in fatality, whereas the deaths from scarlet fever declined. The fatal cases of diarrhoea, which had averaged but 5 during the first five weeks of the current quarter, were 23, 25, and 36 in the three following weeks; the annual death-rate from diarrhoea in Dublin last week was 6.0 per 1000, against 6.7 in the twenty large English towns.

HEALTH MATTERS GENERALLY AT HOME AND ABROAD.

SANITARY TRAINS IN WAR.

The Russian journals contain notices of two works recently published, one a report by the manager of the Red Cross Society on the proceedings of that Society during the late Russo-Turkish war, the other a report of the *état-major* on the work done by sanitary trains during the war. In these reports some interesting particulars are given of the advantages derived from the use of these trains. It would appear that sanitary trains were first used in the war of 1866, and that the experience of their use in the subsequent Franco-German war led to the conclusion that they were available only for the removal of one-third of the sick and wounded from the seat of war. Judging from the experiences of these two wars, it was estimated at the beginning of the Russo-Turkish war that ten trains would suffice for the wants of the Russian army, but the Emperor was asked to authorise the formation of fourteen. At the outset of the war, however, it was found that the larger number was insufficient; and in the end no less than thirty-two trains were organised, each of which was continuously at work for an average period of 465 days. Of the fourteen trains first formed the Red Cross Society undertook the organisation and management of ten. The total number of sick and wounded transported from the seat of war into Russia by the sanitary trains was 218,296, and in addition 40,254 soldiers slightly wounded were sent by ordinary military trains. As to the advantage of these sanitary trains, apart from the fact of their relieving dead-lock from overcrowding in the hospitals at the seat of war, it is noted that 80 per cent. of the patients reached their destination in a state of convalescence. The mortality in the trains in the course of transit was 255. The number of medical men and attendants attached to the trains was 1280, and of these 319 were attacked by contagious maladies whilst on duty. The part taken by the Red Cross Society in this great evacuation of

sick and wounded extended to no less than 106,025 patients, besides the important assistance given generally in the work of transferring the patients to the Russian lines of railway at Jassy, on the Roumanian frontier, where at times the accumulation of patients became all but unmanageable from their great number and the insufficiency of shelter. Occasionally 2000 were despatched to their further destination daily. The report relating to the Red Cross Society refers to the augmented difficulty of their work from the "explosion" of "purple typhus" among the sick and wounded, the disease having been communicated to them by the Turkish prisoners. It is added that all measures to arrest the spread of the malady failed, until the evacuation of the sick and wounded was directed along other routes.

THE VACCINATION ACT, 1880, INDIA.

The preamble of this Act sets forth that it is expedient to give power to prohibit inoculation, and make the vaccination of children compulsory. To this end it is enacted that the Act shall apply only to such municipalities and cantonments situate in the territories administered respectively by the Lieutenant-Governors of the North-Western Provinces and the Punjab, the Chief Commissioners of Oudh, the Central Provinces, British Burmah, Assam, Ajmer, and Coorg, within, in fact, the Presidency of Bengal. Municipalities may adopt the Act by a majority of votes, and local governments may, with the approval of the Governor-General in Council, apply it to cantonments. The Act prohibits any person who may have undergone inoculation from entering within any area where the Act is adopted before the lapse of forty days from the date of operation, and without a medical certificate to the effect that he is no longer likely to spread small-pox. Public vaccinators are to be appointed, and all unprotected children from the age of six months to fourteen years if a boy, and eight years if a girl, where the provisions of the Act are in force, are to be vaccinated. Children who have been vaccinated are to be submitted to the vaccinator for inspection of results. The vaccination of a child is ordinarily to be performed with such lymph as may be prescribed under the Act, provided that, first, if animal-lymph is so prescribed and the parent or guardian of any child desires that such child shall be vaccinated with human lymph, it shall be so vaccinated; and, second, if in any local area in which animal-lymph is procurable human lymph is so prescribed, and the parent or guardian of any child desires that such child should be vaccinated with animal-lymph, and tenders to the vaccinator the amount of such fee, not exceeding one rupee, as may be fixed by such rules in this behalf, such child shall be so vaccinated. No fee is to be charged by public vaccinators. Municipalities and cantonments where the Act is put in force are empowered to frame rules regulating its administration, including, among other matters, the nature of the lymph to be used, and the supply of a sufficient quantity of such lymph. The penalties for breach of the provisions of the Act are severe, the fines being extensible to 50, 500, and even 1000 rupees, according to the provisions violated, and the imprisonment ranging to three and six months.

GAUGING OF PUBLIC SEWERS.

The United States National Board of Health have been causing a series of gaugings of sewers to be made in various parts of the States, with a view of determining the size of conduits needed for the removal of the greatest amount of sewage-matter produced by given populations, or, in other words, to determine the degree to which it would be safe to reduce the sizes of public sewers in cases where the object is only the removal of the foul sewage-matters of households, manufacturing establishments, public institutions, &c. A first report on the subject has been presented to the Board by Mr. Geo. E. Waring, jun., and is published in No. 6 of the Board's bulletin for the current year. The observations are not numerous, but they show how largely the size and cost of sewers may be reduced by the exclusion of storm-water from them. Thus, Mr. Waring observes that when the Commission of the National Board of Health recommended the system since carried out at Memphis of lateral sewers of six inches diameter, and a main outlet of twenty inches, for a prospective population of 60,000, they provided a wide margin for contingencies. He adds: "The result of these investigations cannot fail to be of the greatest practical value, especially in the case of the smaller towns, where the cost of constructing the usual storm-water systems

is so great as to be prohibitory. Incidentally, the advantages to all towns, large or small, of adjusting the size of the sewers to the actual work of removing foul wastes must be regarded as most promising.

DIPHTHERIA IN RUSSIA.

The epidemic of diphtheria in the government of Poltava is reported to be gradually diminishing, and the disinfection of infected houses is being carried out according to the suggestions of Dr. Hübner of the Red Cross Society. A sanitary commission has been established, and in order to facilitate its operations each district has been divided into five or six sanitary subdistricts, and these again into eight or ten quarters. At the head of each subdistrict is placed a medical man, and of each quarter a schoolmaster. For the disinfection of the cottages of the peasants it has been decided by the commission that three pounds of sulphur shall be burnt in each one infected; but in cases where the occupier objects to this process, free ventilation and the burning of vinegar are to be substituted. Diphtheria appeared in the town of Catherinoslaw on the 4th of August. It was believed that the disease had been imported from Bakhmout. The epidemic is declining rapidly in Kiew—thanks, it is said, to the care and energy of the Red Cross Society.

SANITARY CONDITION OF MULLINGAR.

The registrar of Mullingar district, in a recent report, states that it is impossible to carry out the Sanitary Act as intended by the Legislature, owing to the want of a plentiful supply of pure water for drinking purposes and for flushing the sewers, the greater number of which are at the surface, and give off most deleterious gases during the warm weather. The surface sewers on the north side of the town are in a most insanitary condition, owing to the want of flushing, and several of the residents have complained of the nuisance. With reference to the supply of water, there is, it appears, only one well, and that an open one, the water from which Dr. Cameron of Dublin does not consider suitable for drinking purposes; while a large number of the private pumps have been condemned, owing to sewage-contamination, and it is probable that nine-tenths of those at present in use, if examined, would be found equally impure.

THE HEALTH OF CALCUTTA.

Dr. McLeod's report for the second quarter of the year shows that the temperature of the hot season had been "remarkably moderate," with "nothing very remarkable about the humidity, rainfall, and barometric pressure of the month. The price of food had also been "moderate and falling." The fever mortality was low in each month of the quarter, and cholera caused fewer deaths than in the corresponding period of any year in the previous decade. The deaths from diarrhoea and dysentery were also below the average. Ten deaths only were recorded from "the new disease" beri-beri, seven in April and three in May. Dr. McLeod refers to an interesting report on this disease which he had received from Dr. Lovell, the chief medical officer of the colony of Mauritius, where beri-beri appeared in December, 1878, reached its climax in February, 1879, and disappeared in the June of that year, after having caused 729 deaths.

YELLOW FEVER.

In THE LANCET of July 31st we reported, on trustworthy information as we believed, the occurrence of numerous cases of yellow fever on board the Royal Mail Company's steamer *Derwent* on her homeward voyage, and the existence of the disease on board when she touched at Havre. The *Revue d'Hygiène* has made inquiries of the medical officer of health of Havre, Dr. Launay, on the subject, and ascertained that the sickness which occurred on board the *Derwent* was not yellow fever, but bilious remittent fever.

A proposition to establish conduits of water in the city of Samara, first broached by the local authority in 1860, but which proved abortive then for want of funds, and Las to the present year remained dormant for the same reason, has now been revived with hope of a successful issue. A special committee has been appointed by the Municipal Council to consider the question, and the population is hopefully looking for a near future when the supply of water will be abundant.

and the chances of such privation of the fluid as was suffered in 1877 set aside, when, among other incidents, half the city was burned to the ground from the inability to control the flames owing to the deficiency of the water-supply.

THE NEW ROYAL INFIRMARY AT EDINBURGH.

IF we have delayed giving our readers a description of the magnificent new hospital which has been built by public subscription in the Scottish capital, and which was opened for the reception of the sick some ten months since, it is not because we in any way fail to estimate the importance of the undertaking which has been brought to such a successful issue, but rather because we wished to defer a detailed description of the building until it had been in use for some months, and until those who have to work in it had become acquainted with its good as well as, possibly, its weak points. The erection of a hospital at an expense which has been almost unlimited in a city which has been long recognised as one of the capitals of medicine and of thought is no common event, and justifies the expectation that such a combination of circumstances would furnish a building as perfect as it is possible for a building to be in our present state of knowledge, and one which should serve as a model to others, and which should furnish many a useful lesson to architects and sanitarians. These expectations have been, to a great extent, fulfilled, and we shall endeavour to make the reader fully acquainted with the characteristic features of the new building, and in doing so we shall not scruple to draw attention to any points which may seem to us to be susceptible of improvement. Not to be hypercritical upon such an occasion is to fail in our duty, and we feel sure that our Scotch friends would be the first to resent a notice which adopted a merely laudatory and not a critical strain.

The site.—The site chosen for the new infirmary is probably the best which could have been selected, and it appears to us to fulfil every requirement. It is on one of the highest points, and near to the centre of the city, so that it is readily accessible from all points, and therefore is likely to be of maximum utility to the poor whom it is intended to serve. It is close to the University also, so that the students will lose no time in going from their academical to their clinical studies. The ground is eleven and two-thirds acres in extent, and slopes gradually downwards from its most northern to its most southern limit. In this way the drainage of the soil is easily effected, and the whole of the buildings placed upon it receive a maximum amount of sunlight and air. The plot occupied by the infirmary is bounded on the north by the open grounds of George Heriot's Hospital, and on the south by the beautiful public parks known as "The Meadows" and "Bruntsfield Links"; on the east, a broad avenue known as "Meadow-Walk" separates it from the new University buildings, while on the west side is Lauriston-lane. That such a capital site could be found in the middle of a large city is not a little remarkable, and, although we understand that some of the promoters of the new infirmary very strongly wished it to be built upon the site of the old one, we feel sure that few, now the thing is done, will regret the extra expense which the change of site has entailed. The ground, which cost £62,438 10s. 5d., or about £5300 per acre, was previously occupied by George Watson's Hospital, and the architect has cleverly managed to utilise the old building in that block of the new one which is devoted to the nurses and resident students.

General plan.—The plan adopted is that which is now familiarly known as the "pavilion" plan, and it seems probable that in the "pavilion" we have reached a fixed point in hospital construction, from which no very material departure is likely to be made. The administrative block (George Watson's original building) forms the very centre of the plan, and north and south of it are two systems of pavilions, that to the north (consisting of six pavilions) being devoted to surgical cases, and that to the south (consisting

of four pavilions) being devoted to medical cases. All the pavilions run almost due north and south. A corridor connects the northern extremities of the medical or southern system of pavilions. This corridor is only one storey high, so that the space between these pavilions is almost fully exposed to the purifying and sweeping action of both northerly and southerly winds, while a maximum amount of sunlight finds its way into the space because it presents its full surface to the south. The surgical or northern pavilions, six in number, are divided into two groups of three by a great central building, four storeys high, having a handsome turreted clock tower. This building forms one of the chief architectural features of the edifice. It contains a grand entrance-hall and staircase, board room, treasurer's room, and officers' room, and from it run three corridors, the southward to the medical pavilions, and two others east and west to the surgical pavilions. From each of these surgical corridors two pavilions run northward and one southward, so that of the six surgical pavilions four run northward from the connecting corridor, and two (smaller than the others) run southward. The four main surgical pavilions running to the north form, necessarily, three courtyards, each of which is quite open to the north, but more or less closed in to the south. The central court contains an entrance lodge, and is almost completely closed to the south by the four-storeyed main building. From the entrance lodge the ground in this court slopes upwards to the main entrance, which is on the first floor of the main building, and this rise in the ground partially obscures the windows of the lowest wards in the pavilions on either side.

Owing to the main entrance being upon the *first* floor, and to prevent (apparently) the necessity of descending to the ground floor in order to pass to the various pavilions, the connecting corridor of the surgical pavilions is two storeys high (about 30 ft.), and it is obvious that this blocks out to a very serious extent both sunlight and wind. Thus it will be seen that the three surgical pavilion-courts face only to the north, and are very much blocked to the south by the main building and tower, by the two-storeyed corridor, and by other buildings which encroach upon what should have been left as an inlet both for sunlight and for southerly winds. The obscuration of those windows of the lower wards which look upon the central court is also very undesirable. The fact that the main entrance is upon the first floor necessitates a gradual slope in the long corridor which runs southward from it to the medical pavilions. To what extent these undesirable points in the general plan may have been avoidable, we have no means of knowing. They are probably, in part at least, due to the fact that the architect was compelled to utilise the building of "George Watson's Hospital," which has been absorbed into the new infirmary. Great praise is due for the ingenuity shown in making use of this building, which the managers found ready to hand upon the estate which they purchased, but to what extent it may have interfered with the attainment of perfection in the plan of the new infirmary we cannot say.

Each pavilion has three ward-floors and an attic. The height of each pavilion from the ground to the eave of the roof is 46 ft., and from the ground to the ridge 63 ft. The two central medical pavilions are 112 ft. apart, while the two end pavilions are 100 ft. from the more central ones. (In our sketch-plan all the medical pavilions are erroneously represented as equidistant from each other.) The two central surgical pavilions are 158 ft. apart, while the two end ones are only 88 ft. from the central ones. The medical pavilions are 173 ft. 6 in. long, by 33 ft. wide (outside measurement), while the four chief surgical pavilions are 128 ft. by 33 ft. The two surgical pavilions running southward are 59 ft. 6 in. by 28 ft. The surgical or northern frontage of the hospital looking towards Lauriston-lane extends along a line of about 480 ft., while the medical or southern frontage looking over the meadows is about 450 ft. long.

Style.—The style chosen by the architect, Mr. Daniel Bryce, and admirably carried out by his nephew, Mr. John Bryce, is that which is well known as the Scotch Baronial, the prominent features of which are stepped gables and turrets. The material is stone, with slated roofs, and the general effect produced is exceedingly happy. The building is solid, handsome, and imposing, and there is an entire absence of useless and frivolous ornamentation. The tint of the stone, however, is somewhat sombre, and under a grey sky there is a certain gloominess about the edifice not altogether desirable. The free extremities of the pavilions are flanked by turrets in which are placed the sanitary offices of the

FIG. I.—Sketch plan (reduced from a larger plan kindly furnished to us by Mr. John Bryce, the architect), showing the general disposition of the buildings of the Edinburgh Royal Infirmary. A, Central administrative building and grand entrance. B B B, Corridors. C C, Clinical lecture theatres. M M, Medical pavilions. S S, Surgical pavilions. O, Operating theatre. R, Medical reception room. W W, George Watson's original building (deeply shaded), converted into a home for nurses and resident students. X, Students' hall. Y, Casualty room.

FIG. II.—Floor plan of Eastern Medical Pavilion. A, Watercloset. B, Urinal. C, Slop sink. D, Bath-room. E, Lavatory. F, Lobby. W, Ward with twenty-one beds. G G, Fireplaces. H, Nurse's room. J, Doctor's room. K, Private ward. L, Day-room for convalescents. M, Ward-kitchen and sink. N, Bath-room and watercloset. O, Mattress-room. P, Dinner-lift. Q, Patient's lift. R, Dust-shoot and dirty linen shoot, and sink. S, Staircase. T, Corridor.

These sketch plans, made by ourselves, are only approximately accurate.

wards, and one cannot but be struck with the admirable manner in which the Scotch baronial style lends itself to sanitary purposes. We are informed, however, that the turret of the Scotch baron's castle is, so to speak, the real ancestor of the sanitary turret of the modern hospital, and that the baronial turrets were not unfrequently used as latrines, the moat below being the receptacle for the soil. It was often necessary to have two latrine turrets, the one or the other being used according to the direction of the wind, for a hurricane could counteract the laws of gravity, and that which should have fallen into the moat occasionally took a contrary direction.

Details.—We may now consider the arrangements of the pavilions themselves, and if we describe one pavilion it is only necessary to multiply it by ten to get an idea of the entire hospital. Our observations were chiefly made upon an empty ward floor in one of the surgical pavilions, but the arrangements are almost precisely similar, differing only in scale, throughout the hospital. This pavilion, 128 feet long, consists of a low, dry basement, three ward floors, and an attic. The pavilions are 33 feet wide towards their free end, but slightly wider at their attached ends. The eaves are surmounted by stepped gables at the end and sides bearing the chimneys, and pierced with narrow windows to give light to the attic; the towers at the end are each twelve feet in diameter, and are surmounted by conical tops pierced with louvred openings for purposes of ventilation, and surmounted by ornamental vanes. In the middle of the wide attached end of each pavilion is a square louvred turret with conical top and vane, used entirely for ventilating purposes, of which we shall have more to say hereafter.

We will now proceed to the top ward floor of the pavilion and examine its arrangements. Ascending by a stone staircase 6 ft. 6 in. wide, winding in a spacious well-hole some 20 ft. square, we find ourselves in a paved corridor 12 ft. wide by 15 ft. high, from which access is obtained to the six top floors of the surgical pavilions. If the pavilion be an end one the entrance to the ward is flanked on one side by the staircase and on the other side by a food lift, a patient's lift, a little room containing a sink and dust shoot, and also a foul linen shoot. These shoots run right through to the corridor in the basement. We understand that it has already been decided not to use the foul linen shoots, and certainly the dust shoots ought not to be used either, since they open into the lower heated corridor, and quite close to the entrances to the lifts through which heated air charged with impurities has the chance of finding its way to every floor of the building. We hope by this time it is recognised that by perforating a building with vertical shafts, whether for staircases, lifts, or shoots, we diminish to the vanishing point the great principle of separation and isolation which is the only *raison d'être* of pavilion hospitals. Leaving the corridor we enter the pavilion, the ward being approached by a passage some 60 ft. long and 9 ft. wide, giving access on either side to certain apartments which occupy the wide attached portion of each ward floor. These apartments are, on one side a ward-kitchen, a mattress-room, a day-room for convalescent patients, and a nurse's sitting-room looking into the ward; and on the other side a bath-room and W.C., a private ward containing two beds, and a "doctor's room" for examining urine, &c. In addition to these apartments, there is (on the top floor) a small wooden winding staircase, giving access to the attic storey. The entrance to the ward is closed by swing doors, and pushing these aside we find ourselves in the ward itself. This is 75 ft. 8 in. long, 28 ft. 6 in. wide, and 15 ft. high. It contains fourteen beds only, so that each bed has the magnificent allowance of about 153 ft. of area, and about 2300 cubic feet of space. These are amounts which are considerably in excess of those allowed in any other general hospital in the country. Not only is the cubic space allowed to each patient very large, but the means of renewing the air and thoroughly ventilating the ward appear also to be most ample. On either side are seven windows running from about two feet from the floor to within a few inches of the ceiling, and at the free extremity of the ward are two windows and a glass door. The lower three-quarters (about) of the windows open sashwise, but the upper part consists of a pane of glass revolving vertically on an axis. This is opened and shut by an iron rod, and its position being determined by the medical officer or nurse, it is fixed by a simple lock, and cannot be interfered with by patients. In fine weather the windows will afford most ample means of ventilation. In addition to these there are

a number of fresh air inlets, which are situated on the floor level immediately beneath each of the windows. Each of these is about 8 in. square. They are simply channels, running through the walls to the open air, and closed at their outer ends by an iron grating. This grating is closed or opened by means of an iron valve, hinged from the bottom or the top (we saw both arrangements), and worked by means of an iron rod running along the channel to its opening in the ward. The patients' lockers are built into the window recesses, and are fitted round these fresh-air inlets, the length of which they thus practically increase. In some of the wards these inlet channels slope gradually downwards to the outside grating, and one which we measured had a length of 2 ft. 8 in. from the ward to the grating. These channels, about eight inches square, and nearly a yard long, are obviously not easy to clean; and when the channel has a downward slope, and the valve closing the grating is hinged from below, material which rolls or is blown down the slope is stopped by the valve from escaping through the holes in the grating, and it is obvious that no brush would serve to cleanse the somewhat acute angle formed by the floor of the channel and the valve of the grating. In one ward, and only one, we found that portions of an old surgical dressing had lodged in this very spot, and we mention the fact because it is evident that air entering a ward through a dusty or a dirty channel may disseminate much that is, to say the least, undesirable. In the turret-annexes (of which we shall have more to say), a hot-water coil has been placed exactly in front of one of the fresh-air inlets, so that the cleansing of it is thus rendered not merely a matter of difficulty, but an absolute impossibility. It ought to be an axiom of hospital construction that every air inlet should be susceptible of rapid and perfect cleansing. The ward has three open fireplaces, one at each side, and one at the end under the centre window. Two of these are Galton's grates, with inlets (12 in. by 12 in.) above them for warmed fresh air. Exclusive of the windows and doors, the fresh-air inlets are probably nearly sufficient to renew the air in the ward about twice an hour without draught. Fresh air delivery is everywhere horizontal, and nowhere vertical. The ward is equally well provided with outlets for foul air. There are, first of all, the three fireplaces. Beneath each bed is an outlet 6 in. by 9 in. At each of the four corners of the ward there are two large outlets—one near the floor and one near the ceiling; and at either extremity of the ward, close to the ceiling, there are also outlets—twenty-four outlets exclusive of fireplaces and gas flues. These outlets are a very special feature in the hospital. Each of them is connected with a brick flue, terminating on the attic storey in a wooden tube, which travels backwards to the louvred turret placed over the attached end of the pavilion. The attic storey is therefore to a great extent filled by a compact mass of wooden tubes connected with the exhaust flues of the wards below. These tubes terminate round a hot-water tank situated in the louvred turret, and it is intended that the rarefaction of the air in the tubes caused by the heat of the tank shall maintain a constant outflow of foul air through the tubes. This use of hot water as a means of air exhaustion is due to the late Mr. Daniel Bryce. We were not able actually to see the tanks and tube-ends, but we were assured that the outflow of air through the tubes was well maintained. Some of the tubes leading from the lower wards are as much as 200 feet long, and the total length of exhaust tubes in the building must be very considerable indeed. It is hardly possible to think upon such a system as this, ingenious as it undoubtedly is, without sundry misgivings. The chief reflections are, what kind and what amount of matter will collect in one of these long tubes in the course of twelve months, and what possible results may happen in the case of a back current being accidentally established? Supposing, for instance, the hot-water apparatus fails some day in the middle of winter, that the water in the turret tank freezes while a powerful exhaustion is going on through the ward fireplaces, what will happen then? The hospital has been provided with a series of long tubes, having a hot-water tank at one end and three fireplaces at the other, and we did not clearly understand how it has been ensured that the current of air in these tubes shall always be in one direction. When our chimneys smoke (and all chimneys do smoke occasionally) we know the worst of it, and all the material brought back into our rooms is inert and antiseptic. But if a foul exhaust-tube should "smoke," what then? On theoretical grounds we should

hesitate to adopt this system of exhaustion, and we trust that the managers of the Royal Infirmary will take steps to furnish the scientific world with some exact information on the action of these tubes. Two anemometers, each indicating a current in one direction only, should be kept permanently at the ward orifice of each tube in some ward set apart for experiment, and the amount and direction of the daily current during a whole year should be recorded. If it should be established that an occasional puff of air regurgitates from these foul flues into the ward, it is a question whether their potentiality for harm does not altogether outweigh their utility as ventilators.

(To be concluded.)

THE SERVICES.

HEALTH OF TROOPS IN AFGHANISTAN.

THE information which has reached this country respecting the health of the troops on the march from Cabul to Candahar is very satisfactory. The distance from Cabul to Khelat-i-Ghilzai was accomplished in seventeen days, being rather more than fifteen miles a day, with a loss by death of only one European in a force of 2836, and four native soldiers out of 7157, and six camp followers. We may infer from this that every possible attention has been paid to the sanitary condition of the troops. We regret to observe by a letter in the *Times*, signed "An Anxious Mother," that similar care does not seem to have been taken of the troops at Gundamak. In a letter from her son, an extract from which is published, details are given which, if correct, show an utter disregard of sanitary considerations in the selection of the site for a camp at Sufed Sung, and he adds, "The doctors are kicking up a tremendous row about it." We trust the military authorities will cause an investigation to be made into the real facts of the case, and, if substantiated, into the steps taken by the medical officers to prevent so shameful a neglect of sanitary precautions. In former days a medical officer had no power to interfere. Now he has not only the right, but it is his duty to point out to the officer commanding any circumstances likely to affect injuriously the health of the men. It is clear, therefore, that an inquiry should be forthwith instituted to ascertain what representations were made by the medical officer in charge, and whether, finding them disregarded, he made a report in writing to the commanding officer. If he did, the responsibility resting upon the latter is very serious, and unless he can show that it was impossible to carry out the recommendations it will be clearly the duty of the military authorities to take such steps as will prevent the repetition of such utter neglect of the health of the men and disobedience of the standing orders of the service.

NAVAL MEDICAL DEPARTMENT.

Rumours are current that the Admiralty are opposed to making a new grade of rank in their service to correspond with that of brigade-surgeon in the army, but that they are not unwilling to increase the retired pay of fleet surgeons to a maximum of thirty shillings a day, as given in the army to brigade-surgeons. This is strange, and we shall have something to say on the subject hereafter; but for the present suffice it to express the hope that the age at which fleet-surgeons may receive that rate of retired pay will be made to correspond with that at which it is obtainable by brigade-surgeons in the army.

Deputy Surgeon-General H. Hassard, the principal medical officer of the 2nd Division Cabul Field Force, was compelled by ill-health to return to India the last week in July, and will rejoin his appointment at Umballa as the administrative medical officer of the Sirhind Circle.

ADMIRALTY.—The following appointments have been recently made:—Fleet Surgeon Gerald Molloy and Surgeons J. T. Henwood and A. W. May to the *Achilles*; Fleet Surgeon W. H. Adam to the Royal Marine Artillery; Surgeon F. A. Jeans to the *Minotaur*; Staff-Surgeon J. Lamber to the *Tamar*; Staff-Surgeon E. W. Doyle to the *Coquette*.

Staff Surgeon Charles Strickland has been promoted to the rank of Fleet Surgeon in Her Majesty's Fleet, with seniority of 22nd August.

MILITIA MEDICAL DEPARTMENT.—The undermentioned officers resign their commission; also are permitted to retain their rank, and to continue to wear the uniform of their regiments, on their retirement:—Surgeon-Major Samuel Swain Scriven, M.D. (Royal North Gloucester Militia), and Surgeon-Major William Bulmer (5th West York Militia).

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE following special notice has been issued for the information of candidates for the Membership as to the payment of fees for the Primary and Pass Examinations:—

"All candidates presenting themselves for the first time, whether at the primary examination or at the pass examination for the diploma of member, will be subject to the payment of fees in accordance with the provisions of the following bye-law of the College, and all candidates who shall hereafter be rejected at either of these examinations will also be subject to the conditions of the said bye-law:—

"9. The fee of twenty guineas, over and besides the fee for the preliminary examination and the stamp duty, shall be paid by every person prior to his admission as a member. Every candidate for the diploma of member shall, prior to his first admission to the primary professional examination, pay a fee of five guineas, and such fee shall be allowed him as part of the said fee of twenty guineas payable on his admission as a member, and shall be retained whether he pass or fail to pass such examination. No candidate shall, after failure at any primary professional examination, be admitted to a subsequent primary professional examination without paying a further fee of three guineas, which shall be retained whether he pass or fail to pass such examination, but shall not be allowed as part of the said fee of twenty guineas. Every candidate shall, prior to his first and every subsequent admission to the final professional examination, pay a fee of fifteen guineas over and above all charges for stamps; but in every case of failure to pass such examination the sum of ten guineas and the charges for stamps shall be returned to the candidate. The fifteen guineas paid on admission to any final professional examination by a candidate who shall be successful thereat shall be allowed him as part of the said fee of twenty guineas payable on his admission as a member."

Correspondence.

"Audi alteram partem."

FEVER IN MAYO.

To the Editor of THE LANCET.

SIR,—In THE LANCET of Aug. 14th there is given an able and instructive report on fever in Swinford Union, County Mayo. According to that report the climate of Mayo generally, including Swinford, is remarkably damp, rainy, and cold; the condition of the people was that of extreme poverty, their huts affording no more than 200 cubic feet of space to the occupants, the only means of ventilation, the chimney, if such exists, and the chinks in the door; a water-supply from wells, into which sewage-matter of every nature freely passed, collections of filth poisoning the air; a dietary consisting almost exclusively of Indian meal, badly cooked, and often used without milk; in times of distress their clothing pawned; five or six persons sleeping in the one bed, owing to the dearth of bedclothes. The chief types of disease met with were "simple continued and enteric fevers," diarrhoea and dysentery, and typhus. Among the chief features connected with enteric cases are enumerated epistaxis, melæna, emaciation, rachialgia, arthritic, osteal, and abdominal pains, and "the usual relapses of enteric fever." Closely allied to the enteric cases, both as to causation and symptoms, were those of diarrhoea and dysentery; in each it was the rule for all the members of a family to suffer from one or other of these affections; and then, in the statistics given, we are informed that twelve

admissions occurred by "enteric or simple continued fever," but no deaths by "enteric or simple continued fever."

Here, then, it appears to me we have in operation conditions under which disease, adynamic in type, becomes a natural result, whether as fever, diarrhoea, or dysentery. Nothing is stated in the report in question regarding *specific poison*, neither, apparently, was it deemed necessary under the circumstances to assume the operation of other than the conditions enumerated. But with reference to remarks that have been made in some of my papers on fevers among British troops in India, I am induced to believe that the observations now quoted may aid in clearing up certain points in which observers at home and observers abroad seem to experience some little difficulty in mutually understanding each other. The conditions of the climate of Mayo and of the people, as described, are in complete opposition to those under which the soldier in India lives; inasmuch, then, as on the one hand we have in full operation the causes of asthenic disease, so we have on the other—namely, that of the young soldier in India, those of sthenic. An eminent London physician has designated "enteric" fever a *multiform* disease; in the remarks quoted the term enteric is used in connexion, and, to all appearance, synonymously with that of "simple continued" fever; the affection so designated is described as prevailing together with typhus, and it is specially stated that "closely allied to the enteric cases, both as to causation and symptoms, were those of diarrhoea and dysentery." May I, therefore, be permitted to observe that with a view to indicate as clearly as may be the precise nature of the cases in Mayo alluded to as of enteric fever, it would, I think, be useful were a short statement given of—(a) the phenomena and causation, whether specific or non-specific, of the cases so designated; (b) of the precise respects in which they are allied to, or identical with, or different from those of typhus, simple continued fever, diarrhoea, and dysentery, from one or other of which "it was the rule for all the members of a family to suffer" during the epidemic alluded to; (c) the precise significance intended to be conveyed by the term *enteric*—that is, whether as indicating the existence of intestinal disorder in the course of true specific fever, or the presence of a specific form of fever, whether with or without intestinal disorder, or as a synonym of simple continued fever, or if in any other sense, its exact nature. As, according to the high authority alluded to, "enteric or typhoid" fever is *multiform*, it may, perhaps, become practicable, from a consideration of the points above indicated, to learn how far the disease referred to in Mayo represents a separate and independent affection, or a *condition* occurring in the course of others.

I am, Sir, yours, &c.,

C. A. GORDON, Surgeon-General.

Cambridge-gardens, W., August 24th.

ON SCLEROTOMY.

To the Editor of THE LANCET.

SIR.—In his remarks on the treatment of glaucoma by sclerotomy, Mr. Bader has overlooked an important aid to treatment—viz., the use of eserine before and after the operation. There are some cases, and those generally the most severe and urgent, in which the local application of eserine gives no results either in causing contraction of the pupil or in reducing tension, and in these sclerotomy or iridectomy should be at once performed. But a large majority of glaucomatous eyes are very rapidly and beneficially affected by eserine, and its effects are to some extent a guide in the choice of an operation. If the pupil contracts and the tension is perceptibly reduced after repeated use of the drops, there is every prospect of a successful result after sclerotomy; and not only so, the operation is more easily performed, and is less likely to be followed by protrusion of the iris. If, on the other hand, the pupil and the eyeball tension remain unaffected by the eserine, there is still a fair prospect of curing the glaucoma by sclerotomy; but iridectomy is, I think, generally preferable. If, however, a sclerotomy has been performed under such circumstances, the after-use of eserine will often prevent "enclavement" of the iris and its occasionally troublesome effects.

In a paper read by me at a meeting of the Clinical Society in 1876, I ventured to express the opinion that sclerotomy would be "the future remedy for the great majority of cases of glaucoma." I am therefore very glad to hear that the

senior ophthalmic surgeon at Guy's is also in favour of this operation. I cannot quite go so far as he does in thinking that "in course of time the operation will be adopted in every case of glaucoma," but I still think that with the aid of eserine very few cases will require any other operation besides sclerotomy, and that in cases where one sclerotomy seems to have failed it is better to repeat it than to resort to iridectomy. I have now under observation a patient upon whom I performed sclerotomy four years ago. The results are permanent and very good. The occasional loss of an eye from carrying the incision too far back must not be taken as an argument against sclerotomy properly performed. The same thing may and has happened after iridectomy, and possibly, in some instances, from the same cause.

I am, Sir, yours obediently,

W. SPENCER WATSON, F.R.C.S.

Henrietta-street, Cavendish-square, Aug. 25th, 1880.

WOOLSORTERS' FATE.

To the Editor of THE LANCET.

SIR.—In THE LANCET of March 9th, 1878, and again in the No. for December 20th, 1879, appear "annotations" directing attention to the deleterious effects of the dust upon the woolsorters, and it is added that alpaca wool, mohair, &c., seem, besides, to have the power of producing blood-poisoning.

As to mohair, &c., I know nothing, but as to alpaca I beg to offer the following observations:—

Arequipa is the centre of the alpaca trade—nine-tenths of the export passing through this town, and the business is entirely in the hands of foreign houses, chiefly English. The alpaca lives in the interior at heights ranging from twelve to upwards of eighteen thousand feet above the sea-level. The wool is brought down here by mules, ponies, llamas, and a little by railway. When it arrives it is teased out, well shaken, picked, sorted, and then pressed into bales. This work is all performed by women with the exception of the pressing, which, requiring considerable muscular exertion, is done by men. All these manipulations are conducted in sheds which are freely ventilated by natural means. I have frequently visited these sheds, and always found the air highly charged with dust.

And now as to the health of the workpeople. I may premise that I have been in medical charge of the foreign houses for about twenty years. If any of the workers, especially of the old hands, are sick I am requested to see them, as a good woolsorter who is honest—i.e., cannot be bribed to pass bad wool—is a person of value. Upon taking a review of their cases I cannot find anything particular about them. Certainly I find no evidence of any fever (blood-poisoning) or other disease peculiar to them. Even with respect to lung affections, they seem to be no more prone than the rest of the population. In fact, they are perhaps more healthy than their class generally, which may be attributed to their work being light and well paid. On entering these sheds one sees a number of small, somewhat stout, healthy-looking Indian women, some of them with infants. These latter lie about amongst the wool, and are quite healthy. Some of the present sorters may be said to have grown up in the sheds, and yet show no signs of disease. The men are necessarily strong and healthy, otherwise they could not do the work.

Taking a more general view of the subject, I am disposed to think that the bad effects of mere dust—that is, dust which is not seriously irritating, owing to some particular mechanical or chemical property, such as grinders, patent fuel makers, &c.—are exaggerated, and that these effects ought rather to be attributed to badly-ventilated rooms and consequent rebreathing of air, to low pay and consequent bad alimentation. If dust *per se* were so injurious, and not, as a rule, so easily got rid of by the action of the ciliated epithelium of the lung, many more people ought to suffer. Take, for example, the muleteers who travel about this coast. Owing to the scarcity of rain they are from morning to night in a cloud of dust raised by their mules. On arriving at their destination they are thickly covered with dust. These men may get an attack of bronchitis or pneumonia, as they sleep in the open air taking care of their mules, but they are not liable to any form of phthisis or other chronic lung disease.

Allow me to repeat that as to mohair, camel's hair, or

other Eastern wools, I cannot say whether they may give rise to bacillus anthracis or any other form of blood-poisoning; but I think I have proved that alpaca must be held guiltless.

I am, Sir, yours truly,
J. DICKSON HUNTER, M.D. Edin.

Arequipa, Peru, April, 1880.

SUPRAPUBIC PUNCTURE OF THE BLADDER.

To the Editor of THE LANCET.

SIR,—Attention has been recently drawn in your columns to the value of suprapubic puncture of the bladder in cases of retention. This operation has been justly extolled as of great value; and so far as I am aware, the method of puncture adopted when an aspirator is used is considered to be a perfectly safe measure, and to have had so far no case of death recorded against it. I think it might be of use, therefore, to record a case where the results were not so satisfactory.

A few years ago a young man with a history of previous stricture was admitted into the London Hospital with retention that had appeared suddenly after exposure to cold and an outburst of drunkenness. All attempts at catheterism failed, as did also the treatment by hot baths, opium, and a dose of croton oil. The bladder was, therefore, aspirated above the pubes without preliminary incision. Next day the patient passed water spontaneously. On the third day a small catheter was passed, and the patient insisted on leaving the hospital. In less than a week he returned very ill, developed symptoms of pelvic cellulitis, and died in about three weeks. The stricture had given no further trouble. The post-mortem showed no trace of the wound in the bladder, but very extensive suppuration of the pelvic connective tissue.

Another case in the hospital about the same time gave great support to the other side of the question of prognosis. A seaman started on a voyage with a stricture and a medium-sized catheter. He passed the catheter once a week. One day, when on the high seas, he found himself unable to pass either his urine or his instrument, and no surgeon was on board. His symptoms of retention becoming very severe, he deliberately punctured his bladder in the middle line above the pubes with the small blade of a penknife, allowed the water to run out by the side of the knife, and then introduced his catheter into the bladder through the wound. He kept it there until he found he could pass it *via* the urethra. The wound healed well, and the man recovered without an evil symptom.

I remain, Sir, yours faithfully,
FREDERICK TREVES, F.R.C.S.,
Assistant Surgeon and Senior Demonstrator of
Anatomy to the London Hospital.

Gordon-square, W.C., Aug. 1880.

WORK AND PAY IN PROVIDENT DISPENSARIES.

To the Editor of THE LANCET.

SIR,—The subject of Provident Dispensaries being one of considerable importance and interest to the medical profession, I should be glad if you would allow me to publish the following account of one which has been working for two years and a half.

In the beginning of 1878 Messrs. Tangye Brothers, engineers, Cornwall Works, Birmingham, started, at their own expense for twelve months, a Provident Dispensary for their workpeople, their wives and families, after which time their *employés* were to contribute towards its support.

The cost of making certain alterations in a house already existing in connexion with their works, furnishing the same for the resident medical officer, and as waiting and consulting rooms, fitting the dispensary with all necessary appliances, supplying drugs and surgical instruments, together with the salaries of the medical officer and dispenser, was upwards of £1000.

At the end of 1878 it was decided that the *employés* should contribute as follows towards its support: men 4s., women 4s., children over thirteen years of age 4s., other children 1s. 6d., per annum; families consisting of five or more children under thirteen years of age were to pay a

maximum sum of 15s. per annum for attendance upon all members. These sums were not to include attendance in midwifery cases or vaccination, these being left to the discretion of the medical officer.

The services of the medical officer and dispenser were entirely retained for attendance on members of the dispensary.

The following is the account for the six months from January 1st to July 1st, 1880:—

There are now 2890 members, composed as follows: men, 1297; women, 554; children over thirteen years of age, 60; other children, 1056; and 57 families included in the 15s. per annum fee. The total amount received has been £237 0s. 4d. The expenditure has been as follows: salaries of medical officer and dispenser, £191; drugs, £57 12s. 5d.; surgical instruments, &c., £2 8s. 5d.; railway fares, &c., £1 3s. 4d.; rent, rates, and taxes, £17 10s.; sundries (coal, gas, &c.), £6 6s. 9d.; total, £276 0s. 11d. Leaving a deficiency on the half year of £39 0s. 4d.; besides which there is no allowance made for the use of a conveyance, which has been required on an average twice each week.

The amount of work done stands as follows:—The number of fresh cases of illness has been 1728: of these 877 have been men, 280 women, 571 children; 487 have been too ill to come to the dispensary, and have therefore been visited at their own homes, and to these 3078 visits have been paid. There have been 5250 consultations at the dispensary, and 8463 bottles of medicine, &c., have been supplied.

It was thought that it would be of interest to keep an account of the number of men, women, and children visited during the months of May and June; this was accordingly done with the following result: men 25; women 60; children 88; total 173.

I am, Sir, yours faithfully,
CORDLEY BRADFORD, L.R.C.P., M.R.C.S., L.S.A.
Smethwick, August, 1880.

INDIAN MEDICAL SERVICE.

To the Editor of THE LANCET.

SIR,—Several recent numbers of THE LANCET which have reached me show that, contrary to the spirit of the motto which heads your correspondence columns, and in misapprehension I feel quite sure of the actual merits of the case, you have refused admission to letters from officers of the Indian Medical Service on the subject of the recent changes in their Service. Apart from the homely proverb that "they who wear the shoe know best where it pinches," the fact that such a number of letters have been addressed to you, that a deputation had lately an interview with the Secretary of State for India, that numerous petitions are at the present time being submitted to the Viceroy, and that others are in course of presentation to Parliament, might have convinced you that there was "something in" the agitation. There are several events in the history of our service which show that we are far from being an unreasonable body of men. Your strong point appears to be that we are wrong to object to the principle of selection. We are very far from doing so, if the principle is fairly applied, and, indeed, in combination with seniority, it has always governed promotion to the administrative ranks in our service. But what has happened to us is this: that though ours is in its essence a military service, many of us who have stuck to the legitimate, that is the military, line, find that as we are approaching the period at which we might expect promotion, and should undoubtedly have got it under the old rules, it is retarded or altogether taken out of our reach by the administrative rank having been split into two, a military and civil, the appointments in the latter being reserved exclusively for men who have passed most of their service in civil employ. The effect of this rule is that the promotion of some of our most distinguished men has been greatly retarded, and in some cases rendered impossible; for it must be borne in mind that the superannuation rule requires a man to retire at fifty-five if he has not been promoted to deputy surgeon-general; consequently a man who enters the service at twenty-five cannot get promotion at all unless it comes to him within the thirtieth year of his service, and it is exceedingly doubtful whether it will ever under the new rules be attained within that period; seeing that before the split in the administrative grade twenty-six years was an average service on promo-

tion, it is not too much to say that it has been retarded at least four years.

When, in conclusion, I say that this misfortune and disappointment of their hopes has happened to men whose only fault has been that they have stuck to the military line, I think it will be conceded that the widespread dissatisfaction which exists is not to be wondered at. I purposely omit any allusion to the subordination of the military portion to the Army Medical Department, our inferior rank, rates of pension, paucity of honours, &c.

I am, Sir, your obedient servant,

Bengal Presidency, Aug. 4th, 1880.

F.R.C.S. ENG.

** Our correspondent must have read "several recent numbers of THE LANCET" very carelessly if he drew from them the conclusion that we do not think the officers of the I.M.D. have legitimate cause of complaint and very real grievances. But we do not consider exaggerated or incorrect statements to be the most likely means of having them remedied. In the above letter our correspondent writes of "the administrative rank having been split into two, a military and civil, the appointments in the latter being reserved exclusively for those who have passed most of their service in civil employ." But he omits to say on what authority this statement is made, and we are not aware of the existence of any such rule. On the contrary, the General Order regulating the service states that it will be the duty of the Surgeons-General, *inter alia*, "to propose transfers between the military and civil departments; to recommend for promotion to the administrative grades," &c. "Selections will be made in each Presidency from the whole Indian Medical Service of that Presidency, and the principles of selection hitherto followed in making such appointments will be observed." "Although the administration of the Indian Medical Department is divided into two branches, civil and military, Indian medical officers will remain, as now, military officers, those in civil employ being only lent to the civil department."—ED. L.

MEDICAL NOTES IN PARLIAMENT.

In the House of Commons on Thursday, Aug. 26th, a return was presented, on the motion of Mr. Alex. Brown, showing, in a tabular form in order of years, all the local visitations which have been made by medical inspectors, &c.

On Saturday Mr. Stansfeld gave notice that next session he would bring in a bill to repeal the Contagious Diseases Acts.

On Monday Mr. Callan moved for a return, which was ordered, of correspondence between the Inspector-General of Constabulary and the Governors of Dr. Steevens's Hospital relative to the treatment of constabulary patients in the said hospital, referred to in a letter of T. H. Burke, Esq., under-secretary to the secretary of the Board of Superintendence of the Dublin Hospital, under date the 24th day of October, 1878.—Mr. Firth put a series of questions, which appeared in last week's LANCET, as to the destruction at Billingsgate, in the month of July, of ninety tons of fish which was unfit for human food. Mr. Arthur Peel replied that seventy-five tons of the fish came by land carriage, which was more likely to spoil them than carriage by water, and of the remainder twelve tons were taken from a vessel which had lost its stock of ice. The bad condition of the fish was not owing to insufficient market-accommodation, but to the hot weather and dulness of sale, in consequence of the unusually large quantity brought to market in July. Greater facilities for sale would perhaps enable an earlier distribution of the fish to be made; but the Corporation of London denied that their market monopoly was prejudicial to the public. However, they would offer no resistance to the establishment of another market if it were proved to be necessary, and the Home Secretary was willing to consider any well-founded representations which would be made to him on the subject.—Mr. Arthur Moore gave notice that he would make the following inquiries of the Chief Secretary for Ireland: "Whether his attention has been called to the

statement in Dr. McCabe's recent report on Belfast Workhouse, that within the six months from January to June eighty-two infants have died in that institution; and if he would inform the House what percentage of the whole number of infants this represents. Whether in the case of persons not entitled to gratuitous relief, but seeking treatment for infectious diseases in Irish Poor-law hospitals, and willing to pay for the same, there is any regulation which precludes them from using their own clothing, and compels them to adopt the regular pauper-branded garments; and, if such regulations exist, whether he is prepared to modify them, with the view of inducing the middle classes to avail themselves of these hospitals, and thereby raise the standard of medical treatment, and avoid grave dangers to public health."

On Tuesday the sixteenth detailed annual report by the Registrar-General of births, marriages, and deaths in Ireland during the year 1879 was presented.—On the motion of Mr. Bellingham, a return was presented, showing the murders, &c., in England, Wales, and Ireland in three years, ending respectively the 29th day of September and 31st day of December, 1879. Another return, moved for by the same hon. member, was presented, showing how many Boards have availed themselves of the Dispensary Houses (Ireland) Act, 1879.—Dr. Farquharson gave notice of the following questions: To ask the Under Secretary to the Admiralty whether or not it is the intention of the Admiralty, in view of the existing unpopularity of the Naval Medical Service, and the consequent difficulty in obtaining eligible candidates, to take immediate action to remedy the grievances of the Service, and place it on a footing of equality with the Army Medical Service; whether the report of the Committee appointed by the late Board of Admiralty to inquire into the acknowledged grievances of the Naval Medical Department, as announced by the late First Lord of the Admiralty in introducing the Naval Estimates for the current year, has been completed and presented to the Board; and whether or not it is correct that only seven candidates were found eligible during the last twelve months to fill the vacancies, seventy in number, at present existing on the list of naval medical officers.

On Wednesday, a petition for redress of grievances was presented from Surgeon-Major Robert Bird, of the East India Medical Department. A return was presented, on the motion of Mr. Hopwood, of the proportion of deaths from small-pox amongst children in 1847, and from 1855 to 1878. Mr. A. Moore called attention to certain grave abuses and irregularities in the management of Belfast Workhouse, and Mr. Forster promised inquiry into the matter. Subsequently Mr. Moore gave notice that next session he would move a resolution demanding a reform of the Irish Poor Law and its administration.

On Thursday, replying to Mr. Moore, Mr. Forster said the regulations of the workhouse hospitals did not admit of patients wearing their own clothes; and that was a very necessary regulation, as otherwise, if convalescents returned home in the same garments as they had worn in a fever hospital, the disease would quickly spread. At the same time, there was no regulation that patients in a fever hospital should wear the regular pauper garments, and a circular had been issued to guardians forbidding it.—Mr. A. M. Sullivan asked the Secretary of State for War if he would lay upon the table copies of all letters and telegrams relative to the medical appointment offered by the War Office to and accepted by Dr. R. D. Nicolls, of Navan, but which was subsequently prevented, without any explanation to Dr. Nicolls. Mr. Childers said he had looked into the papers in this case, which occurred before he took office. The post accepted by Dr. Nicolls was in the gift, not of the War Office, but of the officer commanding the Navan Division, subject to the approbation of the General commanding in Ireland. The appointment of Dr. Finigan was duly made by them, but some of the communications sent by the War Office to Dr. Finigan were very carelessly written, and he (Mr. Childers) had severely reprimanded the officer in fault.—Sir Henry Peek asked the Secretary of State for War whether his attention had been called to a report made by the officers of health to the Wandsworth Local Board relative to the sanitary condition of the Royal Patriotic Schools on Wandsworth Common, in which it is stated that the sewage lies in pools on the land adjoining the schools, and has been the cause of fever amongst the children? And, whether he proposed to take any steps to prevent these schools becoming a source of danger and disease to the neigh-

bourhood? Mr. Childers replied that he had no authority whatever over the schools of the Patriotic Society. They were managed by a Royal Commission entirely independent of the War Office. To enable him, however, to answer this question, he obtained from the secretary to the Commission an explanation, which he did not consider satisfactory, and he had caused an official communication to be addressed to the Commission.—In answer to Mr. Moore, Mr. Forster said he was making inquiry as to the high rate of mortality amongst the infants in Belfast workhouse, and it appeared to be about 30 per cent.

Obituary.

HENRY FRANCIS BURDETT, M.R.C.S.

WE record with regret the death of Mr. Henry Francis Burdett, Surgeon, of Birmingham. Although Mr. Burdett took little part in questions affecting the politics of the profession, he exercised at one time no inconsiderable influence. He was in all respects a good representative of the general practitioner of a past generation, and with this aspect of his life it may not be uninteresting to deal briefly.

Born at Gilmorton, in Leicestershire, of which place his father, the late Rev. D. J. Burdett, M.A., was the rector, he was sent to Uppingham School at an early age, and remained there till he became apprenticed to the late Mr. Morgan, of Lichfield. He remained with the latter for four years, and then entered at University College, London, where he completed his medical education. He passed the L.S.A. examination in 1836, and became M.R.C.S. Eng. in 1837. Possessed of these qualifications, he married a daughter of Mr. Jones, a surgeon at Lutterworth, and at once settled in Birmingham. Without friends or a connexion of any kind, he began to fight the battle of life with resolution, and, having acquired an exceptionally good knowledge of his profession, his progress was satisfactory and reassuring. In the conduct of his business the chief characteristics of the man soon made themselves conspicuous. Ever intolerant of imposture, Mr. Burdett was noteworthy for the frankness and candour with which he treated all who consulted him. Imbued with a belief that the aim of a general practitioner should be to secure as far as possible cash payments, and such practice mainly as would guarantee a certain income, he soon became surgeon to numerous sick clubs and friendly societies. It was one of his axioms that it is desirable that an account should immediately follow the termination of an attendance. By this method gratitude becomes the stimulus which secures prompt payment. An eloquent speaker, it was his custom to attend the annual gatherings of the Odd Fellows and Foresters. At such meetings his practical eloquence was much appreciated, whilst its forcible common sense led to the effectual removal of many abuses. In a few years Mr. Burdett's practice became a large and increasing one, and till within two years of his death he continued to discharge the active duties of his profession with untiring energy and commendable perseverance. His success was not inconsiderable, for he has left his wife a beautifully situated and fairly large estate at Knowle, Warwickshire, where he latterly resided. His views upon professional subjects were strongly conservative. He could not be got to admit that the new order of things was on the whole better than that of an earlier period, and he held the doctrine that every member of the profession should serve an apprenticeship, and should devote the whole of his time and energies to his profession.

Personally, Mr. Burdett was one of the kindest and most liberal of men. Very many can lovingly testify to this fact, and at his funeral some of his old patients came long distances that they might place a last offering of affection on his grave. The coffin was covered with flowers, and many will sincerely mourn his decease. The deceased gentleman was typical of a class of men who are rapidly disappearing, and we are not sure that their loss to the profession is either small or inconsiderable.

Mr. Burdett died at his country residence, The Coppice, Knowle, Warwickshire, on August 22nd, 1880, and was buried in the family vault at Packwood, in the same county,

on Friday, August 27th. In accordance with the written instructions, found after his death, the funeral was of the plainest possible description—no crape, hat-bands, or plumes were to be seen. He was carried to the grave by eight of his old men-servants; and his coffin bore, by his desire, the inscription—"Henry Francis Burdett, aged 65, formerly a surgeon of Birmingham, and always a firm believer in salvation through our Lord Jesus Christ." He leaves a widow, one daughter, and three sons.

Medical News.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on Aug. 26th:—

Bertolani, John Hewetson, Park-road, New Wandsworth.
Collins, Edward Tenison, Bridge-street, Wednesbury.
Parker, Hibbert Sullivan, Disraeli-road, Putney.
Thomas, John Lloyd, Beaumaris, N. Wales.

The following gentlemen also on the same day passed their Primary Professional Examination:—

William Edward Rauson and Michael William Russell, Middlesex Hospital.

At the recent examination for the prizes in Materia Medica and Pharmaceutical Chemistry, the successful candidates were—

1st.—Arthur William Wheatly, student of St. Bartholomew's Hospital. A Gold Medal.
2nd.—William Watson, student of Guy's Hospital. A Silver Medal and a Book.

A SUM of £1000 has been awarded to the London Hospital by the rector and churchwardens of the parish of St. Edmund the King and Martyr, out of surplus funds of a parish charity of which they are the trustees.

The wife of a labouring man, in the Old Kent-road, was last week delivered of four children at a birth, three boys and a girl; two only have survived. The mother on a previous occasion had given birth to twins.

THE sting of a wasp is stated to have been the immediate cause of the death of a woman at Coggeshall, a few days since. The deceased was, it would appear, the subject of heart disease, and fatal syncope ensued a few minutes after the attack of the insect.

A FRESH series of lectures to the metropolitan police on the first treatment of injured persons has been organised by the St. John Ambulance Association. The classes will meet at Scotland-yard, Arbour-square, Kennington-lane, Blackheath-road, Albany-street, and Twickenham.

LADY HARRIET SCOTT BENTINCK has given £4000 to the International Hospital at Naples, to enable the Committee to acquire a building of their own. It is stated to be one of the conditions of the donation that an English-speaking physician and an English nurse be always kept in the hospital, and that, in case of the dissolution of the hospital, the money be handed over to some other charitable institution of the English community at Naples.

DEATH FROM HYDROPHOBIA.—A little girl died last Tuesday, in Belfast, from hydrophobia. Deceased was bitten by a rabid dog on the 21st of July last, and was conveyed to the Belfast Royal Hospital where, the wound was cauterised. On Saturday last symptoms of the disease manifested themselves, and the sufferer succumbed three days afterwards.

Medical Appointments.

Intimations for this column must be sent DIRECT to the Office of THE LANCET before 9 o'clock on Thursday Morning, at the latest.

ABBOTT, C. E., L.K.Q.C.P.I., M.R.C.S.E., has been appointed Medical Officer for District No. 7 of the Baintree Union.
BENTHALL, A. E., M.R.C.S.E., has been appointed House-Surgeon to the Hartlepool's Hospital and Dispensary, Hartlepool.
BISS, C. Y., M.A., M.B., M.R.C.P.L., M.R.C.S.E., has been appointed Assistant-Physician to the Metropolitan Free Hospital, Spitalfields, London, E.
BROMLEY, J. B., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer for the Tibbury Parish of the Halstead Union.
EDMONDS, W., M.D., F.R.C.S.E., has been appointed Registrar and Chloroformist to the Evelina Hospital for Sick Children, vice Bowlby, resigned.

GALPIN, R., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer for District No. 6 of the Braintree Union.

HAYWARD, J. W., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer and Vaccinator for the Whitstable District of the Bleas Union, vice Mr. Williams, resigned.

HEALE, A. L., M.R.C.S.E., L.S.A.L., has been appointed Surgeon to the Provident Dispensary and Cottage Hospital, the Ladies' Charity, Odd Fellows' Club, and Public Sanatorium, Warwick, vice J. R. Nunn, deceased.

MCBEATH, W., M.D., C.M., has been appointed Medical Officer to the Fourth District of the Eccleshall Bierlow Union.

MCLEARN, I. C., M.D., M.Ch., L.M., has been appointed Medical Superintendent of the Highgate Infirmary, vice Bruce, resigned.

MELLER, C. M., M.D., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer of Health and Public Vaccinator for the Carisbrooke District of the Isle of Wight Union.

MILLS, S. B. A., L.R.C.S.Ed., has been appointed Medical Officer to the Danaghmore Dispensary, Newry Union.

PALMER, B. A., M.D., has been appointed Medical Officer to the Crossmaglen Dispensary, Castleblaney Union.

REYNOLDS, R., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer for the Stambourne and Ridgwell Parishes of the Halstead Union.

RICHARDSON, T. W., M.R.C.S.E., L.S.A.L., has been appointed one of the Medical Officers to the Free and Provident Norwich Dispensary.

SANDFORD, H. V., M.D., has been reappointed Medical Officer of Health for the Combined Rural Sanitary Districts of Bromyard, Hereford, Ledbury, Leominster, and Weobley Unions. Salary £500 per annum.

SIMPSON, T., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer for District No. 5 of the Braintree Union.

THOMSON, R. T. W., M.B., C.M., has been appointed Medical Officer to the Alvington District of the Rothbury Union.

TRIMBLE, C. J., L.R.C.P.Ed., L.R.C.S.L., has been appointed Medical Officer to the Fifth District of the Preston Union.

VAISY, T. F., M.R.C.S.E., L.S.A.L., has been appointed House-Surgeon to the Bucks General Infirmary, vice Blood, resigned.

Births, Marriages, and Deaths.

BIRTHS.

ADAM.—On the 25th ult., at Crichton House, Dumfries, the wife of James Adam, M.D., Medical Superintendent Crichton Royal Institution, of a son.

BULL.—On the 26th ult., at Holland House, New-cross-gate, S.E., the wife of William Bull, F.R.C.S., of a daughter.

GREENHILL.—On the 27th ult., at Cotehele-terrace, Stoke, Devonport, the wife of J. R. Greenhill, F.R.C.S.E., Surgeon-Major, Army Medical Department, of a son.

MITCHELL-BANKS.—On the 26th ult., at Rodney-street, Liverpool, the wife of W. Mitchell-Banks, M.D., F.R.C.S.E., of a son.

PEACOCK.—On the 24th ult., at Forston House, near Dorchester, the wife of Henry George Peacock, L.R.C.P., M.R.C.S.E., of a son.

PRICKETT.—On the 26th ult., at Albion-street, Hyde-park, the wife of Marnaduke Prickett, Esq., M.D., of a son.

PRITCHARD.—On the 29th ult., at South-hill-park, Hampstead, the wife of Urban Pritchard, M.D., F.R.C.S.E., of a son.

MARRIAGES.

ALLCHIN—HOLLAND.—On the 19th ult., at the Church of the Ascension, Esopus, N.Y., William Henry Allchin, M.B., F.R.C.P., of London, to Margaret, elder daughter of Alexander Holland, of New York.

BLACKLEY—BURGESS.—On the 17th ult., at St. John's, Hackney, J. Galley Blackley, M.B., of Gordon-street, Gordon-square, to Fanny Collyer, elder daughter of Frederick J. Burgess, F.R.C.S.E., Ext. L.R.C.P.L., of Grove-place, Hackney.

POOLEY—KENDRICK.—On the 10th ult., at the Parish Church, Bushbury, by the Rev. M. B. Moorhouse, Vicar, assisted by the Rev. R. S. Rowan, Vicar of St. James's, Rochdale, Dr. R. C. Mason Pooley, of Rochdale, to Rosa, second daughter of David Kendrick, Esq., J.P., of Oxley House, Wolverhampton.

WHITE—PULLEN.—On the 25th ult., at the Church of St. Stephen the Martyr, Avenue-road, N.W., O. M. White, M.R.C.S.E., of Tottenham, to Annette Jane, daughter of W. H. Pullen, of Wellington Mansion, St. John's-wood.

WILLIAMS—JEUNE.—On the 25th ult., at The Slad, William Blundell Williams, Esq., M.R.C.S.E., of Much Hadham, to Henrietta Amelia (Amy), younger daughter of the late Lieut. F. A. Jeune, 25th B.N.I., and stepdaughter of John C. Collins, M.D., of Steanbridge, near Stroud.

DEATHS.

LAWRENCE.—On the 31st ult., at Benhall Vicarage, Suffolk, after a short illness, John Travers Lawrence, M.R.C.S.E., of Launceston.

MITCHELL.—On the 31st ult., at 21, Pepys-road, Hatcham, S.E., Robert Mitchell, Surgeon, formerly of Manor House, Deptford, aged 75.

NICHOLAS.—On the 28th ult., accidentally drowned while bathing in the Orwell, Ipswich, George James, second son of G. E. Nicholas, M.D., of Wandsworth, aged 18.

PRITCHARD.—On the 27th ult., at Crescent Lodge, Kingston, near Portsmouth, John Frederick Pritchard, Staff-Surgeon R.N. (retired), third son of the late Vice-Admiral Pritchard, R.N., aged 52.

WAKE.—On the 16th July, at Limocksloof, near Fauresmith, Orange Free State, South Africa, Edward Baldwin, eldest son of E. G. Wake, M.D., of Upper Holloway, aged 20.

WHITMORE.—On the 25th ult., at his residence, Castle Hill, Ealing Dean, John Whitmore, M.D., formerly of Wimpole-street, Medical Officer of Health for Marylebone, in his 70th year.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Local papers containing reports or news-paragraphs should be marked.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

Lectures, original articles, and reports should be written on one side only of the paper.

We cannot prescribe, or recommend practitioners.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET to be addressed "To the Publisher."

THE STUDENTS' NUMBER OF THE LANCET

will be published on Saturday next, Sept. 11th. Those gentlemen holding official situations connected with Medical Institutions in the United Kingdom, who have not yet forwarded the necessary information to our Office for publication in that number, are earnestly requested to send it *without the delay of a single post*.

IGNIPEDITES.

SURGEON-MAJOR B. EVERS, M.D., writing in the *Indian Medical Gazette* on this obscure disease, recommends as the treatment to be adopted the use of iodine and its preparations. The relief following the employment of this drug is, he states, very gradual, and it will only be after a fortnight or three weeks that the patient will recognise that the burning in the soles of the feet is less. Later Dr. Evers administers dilute phosphoric acid, strychnia, quinine, and iron.

Dr. Ruedi, (Davos).—The communication should be forwarded to the magazine in which the article referred to appeared.

THE NITRIC ACID TEST OF URINE.

To the Editor of THE LANCET.

SIR,—I should like if one of your numerous readers could give me, through the medium of your journal, an explanation of the following curious phenomenon:—Twice lately, on adding a few drops of pure nitric acid to some urine which had been boiled, the latter immediately turned to a deep claret colour, with some amount of effervescence. The specimens were both turbid, of a dirty brown colour, loaded with lithates; reaction acid; specific gravity about 1020; a trace of albumen in one, none in the other; no sugar in either; pus in large quantities in both.

I remain, Sir, yours truly,

Cardiff, Aug. 24th, 1880.

* * The development of colour, referred to by our correspondent, on the addition of pure nitric acid to urine that has been boiled has been the subject of much discussion among urologists. The opinion generally held is that it is due to the oxidation changes of indican—a substance which exists in extremely minute quantities in normal urine, and which in some conditions may become increased. The development of the reaction is generally noticed in the urines of patients suffering from wasting diseases, as phthisis, chlorosis, Bright's disease, &c.—ED. L.

TESTS FOR PURE COFFEE.

THE last-issued number of *Cassell's Magazine* contains the following description of some simple tests for the genuineness of coffee:—"Take a little of the coffee and press it between the fingers, or give it a squeeze in the paper in which it is bought. If genuine, it will not form a coherent mass, as coffee grains are hard, and do not readily adhere to each other; but if the grains stick to each other, and form a sort of 'cake,' we may be pretty sure of adulteration in the shape of chicory, for the grains of chicory are softer and more open, and adhere without difficulty when squeezed. Again, if we place a few grains in a saucer, and moisten them with a little cold water, chicory will very quickly become soft like bread-crumbs, while coffee will take a long time to soften. A third test: Take a wineglass or a tumblerful of water, and gently drop a pinch of the ground coffee on the surface of the water without stirring or agitating. Genuine coffee will float for some time, whilst chicory or any other sweet root will soon sink; and chicory or caramel will cause a yellowish or brownish colour to diffuse rapidly through the water, while pure coffee will give no sensible tint under such circumstances for a considerable length of time. 'Coffee mixtures' or 'coffee improvers' should be avoided. They seldom consist of anything but chicory and caramel (burnt sugar), which, of course, deceive by the rich, dark infusion they give."

MEDICAL ETHICS AND PRACTICE IN NEW ZEALAND.

To the Editor of THE LANCET.

SIR,—Having just noticed in No. XIII. of THE LANCET two communications on the title of "Doctor" and "Medical Advertising," I wish to call your attention to the state of these things in this and other colonies.

The Medical Acts here are of such comparatively recent date, and administered with such culpable laxity, that the amount of entirely unqualified work done is very great. Chemists, indeed, all practise openly and without check, denominating themselves on their shop-fronts as "dispensing and prescribing chemists," and indeed often with the sanction of the law, as illustrated by a decision given a short time since by the magistrate of Wellington, in which he acquitted a chemist of *malpraxis* on the ground that he was fit to undertake slight cases, having been the resident dispenser at the hospital for some years. How can any man without a thorough professional education diagnose between a slight case and another? For these reasons the title of "doctor" is universally employed in the colonies, as, whatever qualifications a man holds, he is regarded by the outside public as an unqualified man unless he calls himself "Dr."

Again, in the matter of the reprehensible practice of advertising which you so strongly condemn. The practice prevails here extensively, and it is regarded as so absolutely incumbent on a man starting in a new place to do so, that all do so at first, many permanently. Enclosed I send you a beautiful specimen which I cut out of a New Zealand paper which came into my hands, and in which there were also advertisements by an M.B. Lond. and a German *Æsculapius*. The doctor of the advertisement I send you has the qualifications he describes.

As to any etiquette prevailing amongst practitioners in New Zealand at least, I can only say that it has been an unknown quantity among pretty well all whom I have had the honour of meeting.

Yours &c. (enclosing card),

New Zealand, December, 1879.

DOCTOR.

J. F. N.—The information given by our correspondent is not sufficiently precise. The Warrant to which he refers was issued on October 1st, 1858. If, as seems probable, the training was over by that date, he had not the slightest claim to the allowance at F.O.'s rate, and if it had been issued to him in error, he was bound to refund it.

POISONING BY CHLORAL HYDRATE.

To the Editor of THE LANCET.

SIR,—The amount of chloral hydrate necessary to cause death seems rather uncertain. I should be very glad to know from any of your readers who may have had experience in the matter what they consider the smallest fatal dose for an adult.

I was called in last June to attend a lady, aged forty-seven, who had been suffering severely from neuralgia, and who had spontaneously flown to chloral hydrate for relief. When I arrived I found her insensible, or at least very nearly so. She uttered a few incoherent words at intervals, but did not recognise me, though we were well acquainted. The usual symptoms of poisoning by chloral were present. I found a six-ounce bottle by her bedside containing some solution of chloral hydrate, and which was labeled "Solution of chloral hydrate, ten grains to the drachm." Her friends informed me that this solution had been made up at her request by a neighbouring chemist, and that she had taken several doses during the night; in fact, all that I saw gone from the bottle, which had been quite full. I took home the bottle, and found seventeen drachms absent; in other words, she had taken 170 grains of the drug in about twelve hours. She made a good recovery, but still fails to perceive the danger she had run.

Should a chemist be allowed to sell such a solution to an ordinary customer (with whom he may be acquainted) without having a written order or a physician's prescription?

I am, Sir, yours truly,

A. ST. CLAIR BUXTON.

The Grove, Hammersmith, Aug. 24th, 1880.

Ignoramus.—By the Births and Deaths Registration Act, 1874, sec. 40, it is enacted that "any person who makes any false certificate or declaration under or for the purposes of this Act, or forges or falsifies any such certificate or declaration, or any order under this Act, or, knowing any such certificate, declaration, or order to be false or forged, uses the same as true, or gives or sends the same as true to any person, shall for each offence be liable on summary conviction to a penalty not exceeding ten pounds, and on conviction on indictment to fine or to imprisonment with or without hard labour for a term not exceeding two years, or to penal servitude for a term not exceeding seven years."

Mr. Leighton Kesteven's paper will be published in an early number.

"TREATMENT OF SCARLET FEVER BY WARM BATHS."

To the Editor of THE LANCET.

SIR,—Referring to Dr. Lush's letter in THE LANCET for August 14th, I wish to say that if he adopts the plan of giving three warm baths daily for every scarlatina case he may see, he occasions an unnecessary amount of labour and trouble. An ordinary case of scarlatina requires no such inconvenient treatment, and some very severe cases will not be benefited by it, but will frequently resist any treatment whatever. Dr. Lush's reasons for giving them are—"1st, they bring out the rash; 2nd, lower the temperature; 3rd, comfort the patient." In an ordinary case the first symptom is generally established, and is one of the diagnostic marks of the complaint. The second is also characteristic, and need not be interfered with; it will subside with the rash, or soon after. As to the third, Dr. Lush does not mention the actual temperature of his baths, but I presume them to be between 94° and 98°. This, no doubt, does comfort the patient, just as an ordinary warm bath comforts a person in good health; but I believe it exerts an inappreciable effect on the course of the disease.

In this hospital, where we have special facilities for bathing, we have treated 753 cases of scarlatina, with 94 deaths. Three of the latter have occurred in the warm bath or immediately on emerging. Bathing of some sort is daily employed here in almost all cases for the "comforting" effect, for cleanliness, and for hastening desquamation.

There is one application of the bath where I think I have seen in several cases good to result—at least some of them have recovered. When the patient has been restless, with foul ulcerated throat, offensive discharges from the nose, diffuse swelling about the glands of the neck, little or no rash, blue surface, quick pulse, high temperature or sometimes abnormally low, inability or unwillingness to take nourishment, and a general cadaverous look, I have had him placed in a bath of Condy's fluid and water at a temperature of 100°, and forcibly syringed his nostrils and fauces with the water from the bath, so as thoroughly to remove all offensive matter. Then after five or ten minutes, with only the head above the surface, the contents of a large jug of cold water has been dashed upon the forehead and scalp, an injection of beef-tea and brandy administered, and the patient wrapped up, still wet, in a blanket, and kept warm. Comfortable sleep is nearly always induced, from which the patient generally awakes improved. The treatment sometimes requires to be repeated two or three times at such intervals as the progress of the case suggests. The sleep and quietness produced by this means seem to me to be the main factors in any improved condition of the patient—sleep which cannot safely be procured in any other way that I know of.

The letter from Dr. Smith, of Leamington, published in your issue of to-day, somewhat qualifies Dr. Lush's statement, and I am inclined to think with him that "neither the warm, the tepid, nor the cold bath has any effect on the worst cases."

I am, Sir, your obedient servant,

The Fever Hospital, Bradford, Aug. 28th, 1880.

W. K. RIX.

THE POOR-LAW MEDICAL SERVICE AND COMMISSIONS OF THE PEACE.

To the Editor of THE LANCET.

SIR,—Having been informed, by what appeared to be a reliable authority, that a district or workhouse medical officer would not be able to retain his appointment if placed on the Commission of the Peace, or if acting as a Justice, and feeling it was desirable to get a legal opinion thereon, I wrote to the Local Government Board on the subject, and received the enclosed reply, which it would be well to make public, as I feel satisfied that some Poor-law medical officers have hesitated to accept this distinction from fear of jeopardising their appointments.

I am, Sir, yours obediently,

Soho-square, Aug. 28th, 1880.

JOSEPH ROGERS.

Local Government Board, Whitehall, S.W.,
11th August, 1880.

SIR,—I am directed by the Local Government Board to acknowledge the receipt of your letter of the 30th ultimo, and, with reference to the inquiries which it contains, to inform you that an appointment as medical officer under their Regulations would not legally prevent the person so appointed from being placed on the Commission of the Peace or acting as a Justice. The Board may, however, observe that the Statute 5 and 6 Vict., c. 57, s. 14, would prevent his serving as a guardian so long as he holds the office of medical officer, as they consider that that enactment applies to *ex-officio* as well as to elected guardians.

I am, Sir, your obedient servant,

WALTER J. SENDALL, Assistant-Secretary.

Joseph Rogers, Esq., M.D., 33, Soho-square, W.

Asculapius.—1. The student who had passed the primary examination for the L.R.C.P. Edinburgh, and who desired the diploma of the College of Surgeons of England, would have to pass the primary examination in England as if he had not passed in the Edinburgh College. He would have to do the same if he were a licentiate of the Edinburgh College or Colleges. In reply to our correspondent's second question, we can only answer, No.

ENTERIC FEVER IN TROPICAL CLIMATES: MILK-TREATMENT.

To the Editor of THE LANCET.

SIR,—The letter you publish in your issue of August 28th from Dr. G. Piza Almeida on the subject of typhoid fever touches on a point of considerable importance to my mind.

During the past sixteen years I have treated many cases of enteric fever both at home and abroad, and many years ago I came to the conclusion that a medicine as a cure for the disease did not exist, and that most of the remedies used were positively hurtful. During the past two years I had the opportunity of close daily observation in some twenty cases which occurred in India. Many were fatal, and to prevent the great mortality which is usual in such cases there all kinds of remedies were prescribed, but at the same time "plenty of nourishment" and stimulants were given to "support" the patients, and in my opinion herein lay the fatal mistake. Enteric fever, as I have seen it, whether in England, Central America, or India, is a febrile state, producing or accompanying subacute (verging into acute) inflammation of the gastro-intestinal tract of mucous membrane; and, considering this to be the case, I have always based my treatment on the supposition that everything, whether food or medicine, that passed over that tract while in an inflamed condition, or required an active state of its glandular system, must in the end tend to a fatal issue by the usual consequence of continued irritation—viz., wearing away of the structures implicated, of which mischief purging and hæmorrhage from the bowels are clear indicators.

To find, then, something that, while it would nourish and support the patient during a long illness, would not produce any irritation, or, if it did, the least possible, occupied my attention, and, so far as my own cases go, I was rewarded by not losing a single one. I refer to milk and cream. The moment I had reason to suspect that I was attending a case of enteric fever, I insisted by every means in my power on no other food being given (for twenty-five days if I was certain of the nature of the malady), except milk in various forms. Milk taken cold, two ounces every fifteen minutes, when not asleep, I advised; but patients did not like the too frequent draughts, and used to prefer to take it in larger quantities less often; if in the twenty-four hours two or three quarts were consumed I felt satisfied. Milk made solid by boiling with a small piece of Irish moss made a grateful change, a little cream and sugar being added; or the milk with its curd taken from it, in the form of whey, would be relished by a thirsty patient, with high febrile excitement. Thirst, the patient's greatest friend, is of frequent occurrence. Should the patient yield to the craving for food he so often feels, and take even a slice of bread, it will be almost certain to cause bowel irritation, producing thin stools or bleeding, as the case may be. If a stimulant is needed, a few drops of good brandy in the milk may be taken so long as two teaspoonfuls are not exceeded in the twenty-four hours; but I prefer to do without it if possible. Very little medicine of any kind was called for in my cases: glycerine, in twenty-minim doses, three times a day, or a little castor oil if the bowels are confined, and there is a tendency that way if the milk-treatment is faithfully carried out. I have found a concentrated lime-water added to the milk of use in some cases, but have been surprised how well the milk diet agrees with most people if taken without other food; but it must be persisted in for the entire time the disease is known to run its course, and, as far as my experience goes, that is from twenty-two to twenty-eight days. After the milk diet is begun to be varied, the change must be gradual, and much care and attention paid to local manifestations, should they appear.

I remember well a case that I was called in to see in consultation in India, where the milk-treatment was adopted for sixteen days, and where the doctor attending, thinking all was well and the patient convalescent, yielded to a request, and ordered beef-tea, wine, brandy, and chicken to "nourish the frame," as he told me afterwards, little thinking we would so soon meet together to inquire into the morbid condition of the affected parts on the post-mortem table.

To these remarks I would add that I have seen a persistent high temperature for over fifteen days end in the perfect restoration to health of the patient; and in enteric disease, as we see it in tropical countries, I never lose faith through the readings of the thermometer.

In conclusion, I must say I fully endorse the words of your correspondent when he says, "I do not allow any solid food, but give milk," though I can follow him no further, as I think beef-tea produces often much mischief in enteric fever.

Should this letter be the means of bringing before the notice of physicians the form of treatment I have mentioned, I feel certain that the death-rate of enteric fever, now so high in tropical climates, will fall, till it be regarded as one of the least fatal of all formidable affections the physician is called upon to treat.

I am, Sir, yours faithfully,

J. PERCIVAL HUNT, M.D.

August, 1880.

An Old Subscriber.—The practitioner in question did not act consistently. According to his own statement, he took less than the minimum fee of a physician. He was clearly practising as a general practitioner. The practitioner was a "physician" in the sense of being a licentiate of a College of Physicians, but not in the sense in which the public understand the title. At the same time we cannot quite agree with our correspondent that prescriptions of general practitioners who dispense their medicines are the property of patients. Patients in such a case are supplied with medicines. If, in addition, prescriptions are asked for, it is not unreasonable that a fee should be charged by the practitioner.

HOSPITAL BED CARDS.

To the Editor of THE LANCET.

SIR,—A correspondent asks the opinion of hospital surgeons whether it is advisable to publish the disease under which a patient is suffering by placarding it above his bed. As a hospital surgeon, I decidedly negative the propriety or advantage of this being done. There are many cases in which it is desirable that neither the patient nor the other inmates of the ward should know the disease. There are other cases so doubtful (as in the late Guy's manslaughter) where the physician cannot give a correct diagnosis, and therefore may mislead the nurse (capital was intended to have been made of this at Dr. Pavy's expense). There are also not uncommon instances where the patient, being admitted for one disease, is afterwards found to have another and perhaps a more important malady.

Allow me to mention a point to which your leaders have not alluded. I was in court during Mr. Justice Hawkins's summing up, and he laid very great stress on the inaccuracy of the clinical reports, contrasting the statements therein made with the evidence given by Dr. Pavy, and condemning the discrepancies. Everyone must have felt the justice of his remarks.

As an old Guy's man I have been much pained by the notoriety of recent proceedings there, and sincerely trust that the comments of the learned Judge will induce the authorities of the hospital at once to "set their house in order," and give to the medical officers entire control over the treatment of the patients committed to their charge.

I am, Sir, yours truly,

W.

August, 1880.

Mr. G. R. Gilruth will find the announcement on page 354 of our last number.

Rusty.—Dr. Wickham Legg's.

THE DOSE AND VALUE OF CALCIUM SULPHIDE IN ACNE.

To the Editor of THE LANCET.

SIR,—An article in one of your issues for this year, written by a gentleman whose name I regret I cannot at the moment recall, advocated the use of calcium sulphide in acne, in doses of one-tenth of a grain three times a day, which he cautiously increased in one or two cases to a much larger dose—namely, to one-fourth of a grain—with very excellent effect. The extreme difficulty, and at the same time the great desirability, of adding to those internal remedies which are of real efficacy in the treatment of skin diseases, induced me to follow his example, and to ascertain if possible his reason for cutting down his dose to such very moderate proportions. One opinion only, even when based on repeated observations, has, of course, but a very limited value. However, for what my statements may be worth, I am in a position to say that, commencing with one grain for a dose three times a day, I found no inconvenience experienced by the patients. I therefore increased it by degrees at short intervals up to five grains three times a day in several cases of acne. I am now going on to six grains three times a day, because I have found that a slight feeling of nausea produced by a five-grain dose disappeared speedily on a continuance of the dose. Now, even with this twenty-fold maximum dose, which is apparently tolerated without inconvenience of any kind, I have not, so far as I can judge, done very successfully—that is to say, I failed to effect such a modification of any of the numerous cases of acne in which I have tried it, as may, for example, always be obtained by the inunction of sulphur ointment. I hope that other observers may decide the matter more definitely.

I am, Sir, your obedient servant,

Weymouth-street, W., Aug. 19th, 1880.

BALMANNO SQUIRE.

LOCUM TENENS.

To the Editor of THE LANCET.

SIR,—I have had some considerable experience as a locum tenens, from the consulting physician to the hard-working country practitioner, in practices where fifty visits daily and an average of three midwifery cases weekly, and in others where about five or six visits completed the day's work; but my fee has been invariably the same—£3 3s. per week, with travelling expenses. In one place I should be surrounded with every domestic comfort; in the next the living would be of a most meagre character, treated with suspicion, and the domestic arrangements most uncomfortable. In some I received an extra fee for my services, with thanks; in another I could not even get my fee. Could not some society be formed for registering gentlemen willing to act as locum tenens, and at the same time inquiry be made as to the work, responsibility, and general domestic arrangements of the principal?

I am, Sir, your obedient servant,

August, 1880.

LOCUM TENENS.

URTICARIA.

To the Editor of THE LANCET.

SIR,—May I be allowed to ask, through your columns, whether any of your readers can help me to give a little boy, aged three, relief from very distressing attacks of urticaria. He suffers from habitual constipation, for which he has been treated in many ways. Every six weeks or so this trouble increases so much that nothing but enemata of oil are of any use. The urine shortly becomes scanty and of a deep orange tint, and the urticaria then appears. The spots occur everywhere, even on the face; but the chief distress arises from the soles of the feet, which become completely covered. Three or four doses of magnesia are administered each day, and many local applications have with but slight success been tried—viz., vinegar, tincture of benzoin, lead lotion, spirit lotion, and eau-de-Cologne, the latter seeming to be of the most service. The diet has been carefully looked to, without any benefit in warding off the attacks. It strikes me that in all probability there may be some empirical means known to some by which relief may be obtained, and I should be very grateful for information.

I am, Sir, yours &c.,

August 31st, 1880.

H. H. N., M.R.C.P. Ed.

GUY'S HOSPITAL.—Operations, 1½ P.M., and on Friday at the same hour.
WESTMINSTER HOSPITAL.—Operations, 2 P.M.
WEST LONDON HOSPITAL.—Operations, 3 P.M.

Wednesday, Sept. 8.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.
MIDDLESEX HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1½ P.M., and on Saturday at the same hour.
ST. THOMAS'S HOSPITAL.—Operations, 1½ P.M., and on Saturday at the same hour.
ST. MARY'S HOSPITAL.—Operations, 1½ P.M.
KING'S COLLEGE HOSPITAL.—Operations, 2 P.M., and on Saturday at 1 P.M.
LONDON HOSPITAL.—Operations, 2 P.M., and on Thursday and Saturday at the same hour.
GREAT NORTHERN HOSPITAL.—Operations, 2 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M., and on Saturday at the same hour.
SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2½ P.M.

Thursday, Sept. 9.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—1½ P.M. Surgical Consultations.
CHARING-CROSS HOSPITAL.—Operations, 2 P.M.
CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and on Friday at the same hour.
HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M.

Friday, Sept. 10.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1½ P.M.
ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 2 P.M.
ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

Saturday, Sept. 11.

ROYAL FREE HOSPITAL.—Operations, 2 P.M.

SUBSCRIPTION.

POST FREE TO ANY PART OF THE UNITED KINGDOM.

One Year.....£1 12 6 | Six Months£0 16 3

To CHINA AND INDIA One Year, 1 16 10

To THE COLONIES AND UNITED STATES.. Ditto, 1 14 8

Post Office Orders should be addressed to JOHN CROFT, THE LANCET Office, 423, Strand, London, and made payable at the Post Office, Charing-cross.

Notices of Births, Marriages, and Deaths are charged five shillings.

Cheques to be crossed "London and Westminster Bank."

The above Scale of Charges is arranged upon the basis of the classification adopted in the Index.

NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post-offices letters addressed to initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements (on page 2), which not only affords a ready means of finding any notice, but is in itself an additional advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed.

Advertisements are now received at all Messrs. W. H. Smith and Sons' Railway Bookstalls throughout the United Kingdom.

The postal arrangements relating to the distribution of THE LANCET will be considered from time to time in the interests of subscribers.

Tables of Contents, with the Index of Advertisements, for each Number can be had on application to the Publisher.

Agent for the Advertising Department in France—J. ASTIER, 67, Rue Caumartin, Paris

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 11, 1880.

ADDRESS TO STUDENTS.

HIPPOCRATES begins his famous Aphorisms with the memorable exordium — "Life is short, and Art is long; the occasion fleeting; experience fallacious and judgment difficult." More than two thousand years have passed since "the Physician of Cos" separated Medicine from Speculative Philosophy and gave it a scientific basis. In that long interval a hundred generations of practitioners have come and gone, but the Art of Medicine, surviving the unceasing change of men and manners, has grown in magnitude and grandeur with the lapse of years. Individual lives are short, and one generation follows another in quick succession, but Medicine remains perennial in its youth. The pupil of to-day becomes the master to-morrow, and upon those who are just about to begin the study of Medicine will soon devolve the labour and responsibility of the practice, as well as the duty and privilege of upholding the dignity and extending the scope and usefulness of the Healing Art.

This is a task not to be lightly or capriciously undertaken. More than any other calling in life, the study and practice of Medicine require the happy conjunction of a sound mind in a sound body. No amount of mental vigour will compensate for the absence of physical health. The nature and character of medical studies, as well as the exigencies of medical practice, make calls upon the health and strength that only robust constitutions can meet. During the four or five years of the medical curriculum, at one of the most active periods of physiological growth, the student is compelled to spend a large portion of his time in the vitiated atmosphere of ill-lighted and ill-ventilated lecture-rooms, or in the pernicious air of dissecting-rooms, or amidst the subtler poisons of hospital wards; his only respite being the crowded moments he may snatch for private study. None but strong men pass through this ordeal with impunity, and none but strong men should make the trial. A sound constitution is therefore a prime requisite for those who enter the medical profession; and those to whom this is denied should turn their thoughts to a quieter and a less laborious calling.

Granting a healthy body, the next qualification for a medical student is a tolerably good and a well-trained intellect—an intellect that, in the words of Mr. HUXLEY, is a clear, cold logic-engine, with all its parts of equal strength and in smooth working order. Nature will determine quality, but for the training we must trust to a large extent to the general preliminary education. The best possible form of that education is and always has been a difficult problem.

The preliminary and professional education of a medical student in modern times is different from, but not in all respects better than, that of the student in ancient Greece in the age of PERICLES, or in Italy during the twelfth and thirteenth centuries. HIPPOCRATES is said to have been

taught gymnastics by HERODICUS of Selymbria; rhetoric by GORGAS of Leontini; and philosophy by DEMOCRITUS of Abdera. His knowledge of Medicine he originally acquired by assisting his father in the treatment of patients who resorted to the Asclepion of Cos, and by studying the reports of cases inscribed on the votive tablets that were collected and stored in that famous sanctuary. Later on we shall have occasion to refer to the regulations and restrictions imposed by FREDERICK II. on all who wished to engage in the practice of medicine in the Kingdom of Naples six hundred years ago. It is enough to recall the fact that under that régime some of the best and greatest minds in the Middle Ages were nurtured and matured.

The chief difference between the ancient and the modern constitution is that formerly the curriculum and the prescribed mode of study were trusted to educe the necessary skill and culture, whereas in the present day there is a disposition to disregard the curriculum altogether, and to rely solely upon examination as the measure of attainments. Knowledge, it is alleged, is the only condition of fitness, and examinations are the best and surest means of ascertaining whether the necessary knowledge has been acquired. If the student is equal to the examination-test it matters little how or where he gets his knowledge. It is, however, a fair subject for debate whether this confidence in the efficacy of examinations is not misplaced, and whether a well-arranged curriculum, properly carried out, is not, after all, a better guarantee of culture than any examination, however stringent. A clear distinction must, however, be drawn between the preliminary education and the professional education. The preliminary education, as we shall endeavour to show, should be mainly directed to developing and training the intellectual faculties, whereas the professional is almost wholly technical, and is chiefly concerned in imparting special knowledge and special skill.

As no chain is stronger than its weakest link, and no edifice stable that has shifting foundations, so no training will be effectual that is not based on correct principles. Unhappily, there is a sad want of agreement as to which are correct principles. There are just now at least two rival and contending theories of education—the old and the new, the liberal and the technical, the literary and the scientific. The one aspires to make a man capable and cultured, the other aims at the acquisition of "useful knowledge" and technical skill. The leading principles that seem to characterise the modern theory are—"first," to quote the unapproving words of Mr. JOSEPH PAYNE, "that the curriculum ought to be considered as a counterpart or reflex of the world of knowledge to which it is introductory, and that, therefore, the *omne scibile* of the latter should be represented in the former." The other principle seems to be that as men are often found "unpractised, unprepared, and still to seek," in regard to the circumstances in which they are actually placed in life, we should anticipate the difficulty by making children acquainted beforehand with "the leading kinds of activity which constitute human life"—in other words, "with all varieties of practical business." Stated in its bare simplicity, the theory requires the boy to be provided by his education, "first, with *all scientific knowledge*; and, secondly, with *all practical knowledge*, as his proper equipment for the battle of life." In contra-

distinction to this theory is that which affirms the development and training of a completely-formed and disciplined mind, not the acquisition of knowledge, however valuable in itself, to be the true and proper end of elementary education.

In inquiring into the end of education—and we are now speaking exclusively of general education—it is not enough to appeal to the etymological signification of the word. It does not help us much to say that education means the calling forth of all the mental and bodily powers, if we entertain opposite and contradictory opinions as to the way in which these powers should be called forth. The ultimate end of all education is, says MILTON, to fit a man to perform justly, skilfully, and magnanimously all the offices of life; or, in other words, to fit him for his sphere in life and action, and to make him equal to all the tasks they impose. Education itself is the process by which the individual is enabled to attain this end, and not the end itself, and it should imply the cultivation and improvement of the physical and intellectual powers. The end of musical education is the appreciation and enjoyment of the beauties of Harmony, but the Education involves long and tedious study of dry and uninteresting and apparently irrelevant details. Skill in playing a musical instrument is only acquired by diligent, laborious, and even painful practice. The full fruition is attained only when eye and ear and hand have been made the ready ministers of an educated will. So it is with the work of life. We should seek not “to anticipate the lessons of life, but so to discipline the mind that it may be prepared to learn them from experience.” Herein consists the common error of prescribing for the young and unformed the same methods as for the adult, and the radical fallacy of the vaunted utilitarian theory of education. In the excellent article by Dr. KARL HILLEBRAND on “Half Culture in Germany,” to which we called attention a fortnight ago, it is maintained that the training of the young should tend to develop what is human—that is, common and lasting to all—and that the education should, therefore, be general, and as free from professional tendency as possible, while that of the mature should be directed mainly, if not exclusively, to special or professional subjects and aims. Dr. HILLEBRAND pertinently adds:—“A youth of eighteen, who in our days possessed the classical and mathematical education with which PASCAL and LEIBNITZ left school, would still be completely trained and fully prepared to enter life.”

The dispute, therefore, turns entirely on the estimate of the respective value of the classical languages and mathematics on the one hand, and modern languages, mechanics, and the natural sciences on the other as a means of general education. The advocates of each opinion seem often to forget that either may be good or bad according to the manner in which it is employed. The facts of comparative anatomy, as such, are neither more nor less effectual as aids to culture than the facts of comparative grammar. Their value depends upon the uses they are put to. Book-learned natural science is quite as profitless and more contemptible than the worst evils of the classical system of education.

Even if his judgment could be trusted, the intending medical student has, however, but little to do with deciding what subjects shall be comprised within his general education.

Every portal to the profession is more or less jealously guarded by an examination in the subjects of general education. One or other of these examinations must be passed before the candidate can be registered as a medical student, and, consequently, the officially-recognised medical curriculum can only be begun after the passing of a preliminary examination. Though the standard varies within very wide limits, there is great similarity in the nature and number of the subjects required by the various examining boards. With an almost identical list of subjects, one board may not require a higher standard than a boy of moderate industry and average intelligence may touch by the time he is fifteen years of age, while another board may pitch its standard so high that only industrious young men of seventeen or eighteen can reach it. In deciding at which board he will present himself for his preliminary examination, the student should select that which implies the best general culture. It need not be the most difficult examination; indeed, preparation for such an examination is not unfrequently preventive of true culture. Lastly, the student should not be in too great a hurry to bring his preliminary education to a close. His desire should be to obtain the best general education he can, though in doing so he may have to postpone his strictly medical studies for a year or two.

We must not, in these observations, be supposed to sympathise with that form of priggishness which prompts a young man to prate everlastingly about the improvement of what he is pleased to call his mind. There are some men who constantly strain after an impracticable ideal of moral excellence, while they neglect the exercise of the ordinary public and domestic virtues, and others give themselves up so completely to the labour of improving their minds that they never make any decent use of the brains that Nature has given them. It is as if a man should expect to become a skilled performer by cleaning and polishing the internal mechanism of a musical instrument. What everyone who wishes to do any good in the world has to learn is to make the best use of his native powers. It is not enough to accumulate a confused heap of intellectual bricks and mortar; we need likewise the skill to put them together. Nor, on the other hand, will architectural skill avail without the bricks and mortar. A well-stored memory, under the guidance and control of a robust and disciplined intellect, is the best attainable outcome of any system of education. It ought, therefore, to be borne in mind that, although the preliminary education should be as general as possible, it should nevertheless be so planned that the special training of after-life may be added to it. In addition to the ordinary subjects of general education, not omitting the despised smattering of Latin and Greek, the would-be medical student should at least have a reading acquaintance with both German and French, and should likewise know something about one or more of the various branches of natural science. There is no department of natural science at all comparable with botany as a training for the youth of both sexes. Properly pursued, it is calculated to promote health and physical well-being, and to train the mental faculties in the scientific method. In no other department of science do the same facilities occur for complying with all the conditions of inductive philosophy—namely, observation, comparison, classification, and generalisation.

The student having obtained the best general education his means or abilities will allow, his thoughts will naturally turn to his medical career. In what way is this to be entered upon? Formerly, the almost invariable custom was by way of apprenticeship; but of late years the system of apprenticeship has grown into disfavour, and the medical curriculum is now commonly begun and ended at a medical school. Many circumstances have conspired to bring the apprenticeship system into abeyance. The predisposing cause was, perhaps, the common disregard of the conditions of apprenticeship both by principal and pupil. The essence of apprenticeship is that a master binds himself to teach, and the apprentice undertakes to learn, some art or profession. But in the medical profession, as in most other callings, the master usually forgot to teach, and the pupil, after the subsidence of his first flutter of enthusiasm, did not care to take the trouble to learn. The pupil became, as it were, an irregular, unpaid assistant. Another blow to the system was the passing of the Medical Act, and the compulsory registration of legally-qualified practitioners. From the time of the passing of this Act examinations have more and more been relied upon both by the profession and the public as a final and sufficient test of fitness. No one can have his name enrolled on the Medical Register without passing an appropriate examination, and the public is satisfied with the protection which examinations are supposed to afford. Moreover, when it was discovered that those who had not served an apprenticeship had, if anything, rather less difficulty in passing these examinations than those who had, there gradually arose a natural disinclination to pay a large premium for the equivocal privilege of acting as errand boy, book-keeper, dispenser, and unqualified assistant to a general practitioner. Though it may be true that the system of apprenticeship was flagrantly abused, there are some reasons for doubting the wisdom of discontinuing it altogether, and of relying exclusively upon the observance of a prescribed course of study, and the imposition of examinations to provide competent practitioners. The successful practice of medicine does not consist wholly in merely physical diagnosis and the administration of particular nostrums. There is often something more than the mere pathological lesion to be looked to—there is the intricately complex assemblage of emotions and passions, and feelings and prejudices, which we call *man*, to be thought of and considered. This requires a combination of perspicacity, tact, and judgment that can only be learned by experience, and cannot be imparted. Physicians of all ages have recognised this fact. In ancient Greece physicians paid great attention to the study of philosophy and rhetoric, in order to understand the mental and moral constitution of man, and to control or counteract the effects of his caprice. When HIPPOCRATES rebuts the opinion that it is not possible for anyone to know medicine who does not also know what man is, and how he was made and constructed, it is against the delusions of the Sophists and their specious fallacies, and not against true philosophy, that he protests. For a similar reason, no one was allowed to study medicine at Salerno who had not gone through a prolonged course of study in logic. In the absence of a similar provision now-a-days, it would not be amiss for an intending medical student to spend twelve months under the surveil-

lance of an educated and experienced practitioner. If judiciously observed this arrangement would afford an excellent introduction to the stricter instruction at a medical school. During that twelve months the student might learn enough of Chemistry, Pharmacy, Materia Medica, Osteology, and Elementary Physiology to enable him to take an immediate and intelligent interest in these subjects, when he does enter a medical school.

Another advantage of a short pupilage would be a salutary break between the restraint of school life and the sudden and uncontrolled freedom of city life. If the time were not wholly wasted, not only would useful knowledge be gained, but the character would be more established, the sense of responsibility heightened, and the natural disinclination to work corrected and removed.

In another respect we might imitate some of the older regulations, and especially those in force at the University of Salerno. Not only was the preparatory study of logic for three years insisted on at Salerno, but the subsequent medical curriculum extended over a further period of five years. When this was completed the student had to pass two examinations, and then to spend at least a year on trial with an experienced practitioner before he was allowed to engage in practice on his own account. Notwithstanding the enormous increase in the number and complexity of the facts now to be learned by a medical student, the ordinary medical curriculum occupies little more than half the time it did six hundred years ago. Short as it is, there are not a few persons, believers in the unfailing efficacy of examinations, who would abbreviate it still more. Against the prudence of such a proposal much might be said; though it is not our present object to propose or oppose any reforms, but rather to encourage the student to bring to his medical studies the best general culture he can, and then to devote the longest time he may to learning the Science and Art of Medicine.

Little need be said here of the way in which this time should be spent. This will be mainly determined by existing arrangements and regulations. At the beginning of his medical career the student will have to conform to the Method of Instruction, following implicitly the authority of his books and the utterances of his teachers. Soon, however, he will have to supplement instruction by observation. Then will he enter the threshold of that method which has been of such signal service to mankind. From observation he will proceed by easy stages to comparison, and from comparison to classification, thence to generalisation, till he finally discovers that Identity amidst Diversity which Professor JEVONS tells us is the real business of Science. The student will then perceive the difference between his general education and his professional, and the direct bearing of his studies on his future career. His education is, in fact, entirely technical: he is learning to do something, to qualify himself for a calling.

In this calling, happily, moderate talents honestly employed may effect much. Though medicine and the allied sciences afford plenty of scope for the highest efforts of genius, yet humble talents may never despair of doing useful and honourable work. Sir ISAAC NEWTON was wont to declare that whatever service he had done to the public was not owing to any extraordinary sagacity, but solely to industry

and patient thought; and Dr. THOMAS YOUNG, the brightest ornament of our profession, famed alike as a philologist, philosopher, and physician, had little faith in any peculiar gifts of genius. The original intellectual differences between men he believed to be much less than commonly supposed. He was himself one of the most conspicuous examples of unflagging industry and uncompromising thoroughness, and he often quoted with approval the lines from some stanzas addressed by Dr. BARNARD to Sir JOSHUA REYNOLDS:—

"Then say'st not only skill is gained,
But genius too may be obtained,
By studious imitation."

CHANGES IN THE MEDICAL SCHOOLS AND HOSPITALS.

THE changes during the past year have been comparatively few and unimportant, and not more than may be reasonably accounted for by the natural progress of events. Though one or two well-known and respected names are missing from the lists, the death-roll is neither so long nor so saddening as it was last year. In London, Charing-cross Hospital has lost its venerated Consulting-Surgeon, Mr. Hancock; King's College its accomplished Ophthalmic Surgeon, Mr. Soelberg Wells; and St. Bartholomew's its best-known Surgeon, Mr. Callender. The Leeds School has been robbed of its trusty friend and supporter, Dr. Heaton; and Manchester has lost a promising surgeon by the death of Mr. Bradley.

At *Charing-cross* the Hospital has lost its senior consulting surgeon by the death of Mr. Henry Hancock, and Dr. Lees has migrated to St. Mary's. In the *School* the only change is that Dr. W. Houghton has succeeded the Rev. J. C. Saunders as lecturer on Botany.

At *Guy's* the only change is the appointment of Mr. H. Moon, as full dental surgeon, *vice* Mr. Salter.

At *King's College* Mr. Cheyne has been appointed one of the demonstrators of Surgery, and assistant-surgeon to the hospital, in place of Mr. Gerald Yeo, resigned; and Mr. McHardy has been appointed professor of Ophthalmology, and ophthalmic surgeon to the hospital, *vice* Mr. Soelberg Wells, deceased.

At the *London Hospital* Dr. Ramskill has been appointed consulting physician, and Dr. Fenwick full physician. Dr. F. Warner and Dr. Ralfe have been appointed assistant physicians, and Mr. F. Treves has been appointed assistant surgeon. In the *School* Dr. S. Mackenzie has succeeded Dr. Sutton as lecturer on Medicine, and Mr. James Adams has succeeded Mr. Couper as lecturer on Surgery, and the late Mr. Maunder as teacher of Operative Surgery. The other changes are Mr. Treves, teacher of practical anatomy, *vice* Dr. Wilson, resigned; Dr. Warner, lecturer on Botany; and Dr. H. G. Sutton, lecturer on Pathology, in place of Dr. S. Mackenzie. Mr. Munro Scott has succeeded as warden Dr. Norman Chevers, resigned.

At the *Middlesex Hospital* Dr. Greenhow has been made consulting-physician, and Dr. Coupland promoted to the rank of full physician. Dr. J. K. Fowler has been appointed assistant-physician, and Mr. Arthur Hensman, aural surgeon.

At *St. Bartholomew's* Mr. Willett has been promoted to a full surgeoncy, *vice* Mr. Callender, deceased; and Mr. Butlin has been appointed assistant-surgeon. In the *School* Mr. Bruce-Clarke, Mr. Edwards, and Mr. Griffith have succeeded Messrs. Roeckel and Shuter as assistant demonstrators of Anatomy.

At *St. George's Hospital* Mr. Pollock has been made

consulting-surgeon; Mr. Haward full surgeon; and Mr. W. H. Bennett and Mr. Dent have been appointed assistant-surgeons. In the *School* Mr. Stirling has succeeded Dr. Cavafy as lecturer on Physiology, Dr. Ewart has succeeded Dr. Ralfe as lecturer on Physiological Chemistry, Mr. Bennett has succeeded Mr. Stirling as lecturer on Histology, Mr. Donkin has succeeded Mr. Wanklyn as lecturer on Chemistry, and Dr. Owen has succeeded Dr. Ewart as lecturer on Morbid Anatomy.

At *St. Mary's Hospital* Dr. Lees has been appointed assistant-physician, *vice* Dr. Farquharson, M.P., resigned; and Mr. Malcolm Morris has succeeded the latter gentleman in the Skin Department. Mr. Pepper has been appointed supernumerary assistant-surgeon. In the *School* the only changes are, Mr. Pepper, lecturer on Histology, *vice* Dr. Shepherd, resigned; and Dr. Shepherd has been appointed joint-lecturer with Dr. Cheadle on Pathology.

At *St. Thomas's Hospital* Dr. Sharkey has been appointed assistant-physician, and Mr. Anderson assistant-surgeon. Dr. Gulliver has succeeded Dr. Sharkey as resident assistant-physician. In the *School* Dr. Sharkey has been appointed additional lecturer on Physiology; and Dr. Payne collector with Dr. Greenfield on Pathological Anatomy.

At *University College Hospital* Dr. Roberts has been made full physician; and Dr. T. Barlow has been appointed assistant-physician, and Mr. J. W. Bond resident medical officer. In the *College* Dr. Poore has succeeded Dr. Maudsley as Professor of Medical Jurisprudence.

At the *Westminster Hospital* there have been no changes.

At *Queen's College, Birmingham*, at the *Bristol Medical School*, and at *Cambridge* there have been no material changes.

At *Leeds*, Dr. Churton has been appointed lecturer on Clinical Medicine and physician to the Infirmary, in place of Dr. Heaton, deceased.

At *Newcastle-on-Tyne* (University of Durham) Dr. Oliver has been appointed lecturer on Practical Physiology.

At *Liverpool* there are no changes.

At *Manchester* (Owens College) the vacancies caused by the death of Mr. Bradley have not been filled up yet.

At the *Sheffield Medical School* there have been no changes.

At the *University of Aberdeen* and at the *University of Edinburgh* there have been no changes, except the appointment of Mr. A. Smart as assistant-physician to the Infirmary in Edinburgh.

At the *University of Glasgow* the only changes are the appointment of Dr. Charteris as professor of *Materia Medica*, *vice* Dr. Cowan; the appointment of Dr. Bayley Balfour as professor of Botany; and the appointment of Dr. Yellowlees as lecturer on Insanity.

At the *Glasgow Royal Infirmary* Dr. Johnstone Macfie has succeeded Dr. Cassells as aural surgeon.

At the *University of Dublin* Dr. Macalister has succeeded Dr. McDavel as professor of Anatomy.

At *Carmichael College, Dublin*, Dr. Francis Henston has been appointed lecturer on Systemic Anatomy.

ON BOOKS.

ALTHOUGH the only sound knowledge is that obtained from personal observation and practice, yet no one would imagine that these sufficed for thorough education. There are many things in medicine which, to be sure, can only be learnt by oral precept and practical example; but there is neither time nor opportunity for the student in the present day to learn the whole of his art by these means, whilst the science (if it may be so called) of medicine is only to be learnt in books. Hence the student must, if he wish to be

thoroughly schooled, devote a considerable portion of his time to reading. Of course, he must not err on the other side, and degenerate into a bookworm; for his concern in after-life is with matters of practical import, involving the prompt recognition of the features of disease or injury, and the decision as to the choice of appropriate treatment. Reading will not furnish him with all his knowledge, but it will enable him to store his mind with facts of great importance and value.

Whilst, then, he should be careful not to absorb too much of his time in the perusal of books, he should endeavour to devote an adequate amount of time to it, and should always seek to read with a definite purpose and understanding. In this country we are especially rich in text-books, and many of them so good and excellent that it is difficult to choose between them. It would not be possible to enumerate them all here; we cannot attempt anything like a complete catalogue; but we may indicate some of those which are best known and in most frequent use. There may be some of equal excellence which we have failed to name, and we may have mentioned some which few students have time or opportunity to read. We would urge especially upon the student not to be discursive in his reading; but, having made his choice, to adhere to his text-book and study it carefully. It is far better to know one book well than to try to absorb a smattering of many. Occasionally he may find it necessary for the sake of elucidation to refer to some larger treatise, which will probably be found in his school library; and he will do well to make a careful note of the point which has puzzled him, and not to be satisfied until he understands it. For it is of great importance that he should be master of what he has read. Many make the mistake of getting through so many pages in so much time, vainly imagining that the amount of reading represents so much knowledge acquired. Few fallacies are greater than this. The acquisition of real knowledge is a slow and laborious process, and the student must not shrink from repetitions, until he really feels secure of the facts he has gleaned. His reading, then, must be slow and steady, and the reverse of spasmodic; he should take his intellectual food as regularly as his meals. All men are not born students, but all can, if they will—and it is a duty they owe to themselves—do their utmost to study in a methodical and uninterrupted manner. There ought to be no break in the continuity of their labours, but they must go on acquiring knowledge bit by bit, and thus lay the foundations of that which is to be their life-pursuit.

We will now proceed to our enumeration of authors, placing those first who have written the more elementary works. The books of reference, &c., are named afterwards.

Chemistry.—Barff, Roscoe; Williamson, Attfield, Fownes; Miller, Roscoe and Schorlemmer. Of these Professor Barff's "Introduction" is suitable to the beginner, but its scope is too limited for the requirements of any of the medical examining boards. Roscoe's "Elementary Chemistry" travels over the whole range of the subject, and will, if thoroughly mastered, prove more than sufficient. The like is true of Fownes's well-known work, which has been brought up to the modern standpoint by recent editors. For a compact but clearly-reasoned book, the student cannot do wrong if he prefer Professor Williamson's work; and those who have time at their disposal, or are ambitious of university honours, the work of Professor Miller, or the last-named on the above list, may be consulted or read. Miller's book has a volume devoted to the subject of Physics.

Practical Chemistry.—Odling, Bowman, Attfield. These books are each of them useful to the student who has not the advantage of personal supervision of his work at the hands of the teacher, or their perusal may profitably be undertaken in conjunction with the practical study of the subject.

Natural Philosophy.—Newth, Ganot; Deschanel, Thomson and Tait; Balfour Stewart, Tyndall. In this subject, which is required for the "preliminary scientific" examinations, but does not enter into the ordinary curriculum, some of the pleasantest books to read are Ganot's Physics and the works on Heat, Sound, and Electricity by Prof. Tyndall,—these latter being books that may be read in hours of comparative leisure, for they are penned by one of the clearest expounders of scientific truths extant. Similar subjects are dealt with in Deschanel's treatise, which may be obtained in separate parts; and Balfour Stewart's work on Heat is widely recognised as one of the best in the language. The large "Natural Philosophy" of Thomson and Tait can only be regarded as a work of reference for most students.

Botany.—Cooke, Silver, Oliver; Balfour, Bentley, Sachs. *Atlas:* Bentley and Trimen. Several works are to be had of an elementary character; that of Mr. Cooke on "Structural Botany" or the little "Outlines" of Dr. Silver are good. Oliver's "Elementary Botany" has met with well-deserved success, and recently translations of some foreign works have appeared. Balfour's work has long been a favourite, and Bentley's is also much read. Messrs. Churchill have recently completed the publication of an excellent Atlas of "Medicinal Plants," under the joint authorship of Professor Bentley and Mr. Trimen—a work which should find a place in the library of every medical school.

Zoology and Comparative Anatomy.—Bradley, Ord; Nicholson, Huxley, Rymer Jones, Gegenbaur; Flower, Rolleston, Huxley and Martin. For practical work in this subject no better guide could be mentioned than the last-named, and of a severer class is Prof. Rolleston's "Forms of Animal Life." In systematic zoology the various works of Prof. Nicholson have been very popular. They have replaced the well-known text-book of Rymer Jones; and those who wish to go deeper into the subject should not fail to read Prof. Huxley's "Vertebrata" and "Invertebrata"; the same author's "Introduction" being, we believe, now out of print. The recent translation of Gegenbaur's manual serves to complete a list of writings on a subject upon which ten years ago English literature was very defective, and candidates for University degrees could not do better than make this their text-book. For clear and concise summaries, Mr. Bradley's and Dr. Ord's smaller works may be recommended. Prof. Flower's "Osteology of Mammalia" is the only work of its kind, and its study would add much interest to the dry details of human osteology.

Anatomy.—*Systematic:* Quain, Gray. *Practical:* Ellis, Holden, Heath, Ledwich, Hensman. *Osteology:* Ward, Holden, Norton, Wagstaff. *Arthrology:* Morris. *Regional Anatomy:* Holden, Smith and Walsham. *Plates:* Ellis, Godlee, Braune, Sibson.—In this subject, which occupies so much of the student's time in the first two years, there are very numerous works, some of which are better consulted in the study, and others are written for constant use in the dissecting-room. For the latter purpose the most complete and trustworthy is Professor Ellis's Demonstrations in Anatomy, which has stood the test of quite a generation of students, and is apparently as much appreciated as ever. Similar excellent guides are the smaller works of Heath, Holden, and Ledwich. For the systematic study of the subject Gray's Anatomy has long been a favourite, and holds a well-deserved place in the estimation of students; whilst the book which has obtained a wide-world reputation is Quain's Anatomy, the representative work of English anatomical science. Several books have been written upon osteology alone, the subject which faces the student at the outset of his career; of them the most exhaustive and best is undoubtedly Ward's; but Holden's work is perhaps much more widely read, and it is very excellent. The only work specially devoted to the anatomy of the joints is that by Mr. Henry Morris, which may be consulted with advantage. Valuable for the assistance they afford in recalling the parts dissected, and very useful therefore when the student cannot be engaged in his practical pursuits, are the excellent "Plates" of Ellis and those in the Atlas (just completed) of Mr. Rickman Godlee. To those who wish to better impress the memory with the facts they observe, the "Outlines" of Mr. Hensman may be filled in by the pencil with the dissected part before the eyes. In the department of regional anatomy there are the plates of Professor Braune, with English text by Mr. Bellamy, and Sibson's work on medical anatomy; whilst smaller works dealing with "Landmarks" are those of Holden, Smith, and Walsham.

Physiology.—Huxley; Kirkes, McKendrick; Marshall, Foster, Hermann, Carpenter, Flint. To those who come to a medical school without any previous knowledge of the subject, no better book to begin with can be recommended than Professor Huxley's elementary work. But this, of course, will not suffice for the whole education of the medical student in this most important subject. The well-known text-book of Kirkes is, of all the works on this subject, by far the most popular. It has run through many editions, and a new one is announced to appear this session. Almost as popular, but less attractive to the general student, is the text-book by Michael Foster, which it is incumbent upon the aspirant for higher diplomas to read. Of the same scope as Kirkes may be mentioned the manuals by McKend-

rick, Marshall, and Küss; whilst Carpenter's large work has always maintained an excellent position, although it has been somewhat superseded by newer and less cumbersome books. The works of Hermann and of Flint have also obtained a well-deserved position in this country. Upon *Physiological Chemistry* the student will find a useful guide in Dr. Ralfe's little book.

Histology.—Quain's *Anatomy*, vol. i.; Gray's *Anatomy*, Introductory Chapter; Schäfer, Rutherford; Stricker; Klein and Smith's *Atlas*. A fairly exhaustive account of histology is to be found in some of the books mentioned in the last section, but for the most complete treatise on the subject Quain's *Anatomy* continues to hold the first place, the large work by Stricker (Syd. Soc. Ed.) being necessarily too exhaustive for the ordinary student. Prof. Schäfer's little work is the most thorough guide on the subject of practical histology, and Rutherford's "Outlines" are also excellent.

Practical Physiology.—Power and Kidd, Foster and Langley, Sanderson. For laboratory guides the two first-named are sufficient, and the larger "Handbook" edited by Dr. Sanderson should be referred to for further details.

Materia Medica and Therapeutics.—Brunton, Thorowgood, Milne, Farquharson, Garrod, Scoresby-Jackson; Wood, Phillips, Ringer, Waring, and Fothergill. In *Materia Medica* Dr. Garrod's and Scoresby-Jackson's works are good, and of smaller size are the compendia of Thorowgood, Royle, Farquharson, and Milne, whilst the "Tables" of Brunton are intended to facilitate the student's labour in this somewhat arid subject. Wood's and Phillips' works are both of them of a high class, the best, perhaps, in the language; they deal largely with the physiological action of drugs. Upon the more interesting subject of practical therapeutics, that which has been most widely read is Dr. Ringer's handbook; and the works of Dr. Waring and of Milner Fothergill also abound in useful hints and suggestions.

Medical Jurisprudence.—Guy, Taylor; Tidy and Woodman. In this subject the books most suitable for students are Taylor's *Manual* and Guy's "Forensic Medicine," which embrace all branches of the subject; but Taylor's "On Poisons," and his larger work on "Medical Jurisprudence," may profitably be referred to; as also may be the rather unwieldy book published two years ago from the pens of Drs. Tidy and Woodman.

Medicine.—General: Tanner, Roberts, Bristowe; Aitken, Niemeyer, Flint, Watson; Reynolds, Trousseau. *Nervous Diseases*: Wilks, Charcot, Althaus, Hammond, Bastian, Rosenthal, Gowers. *Diseases of the Heart*: Walshe, Balfour, Fothergill, Hayden. *Diseases of the Lungs*: Walshe, D. Powell. *Diseases of the Kidney*: Roberts, Dickinson, Stewart, Johnson and Beale. *Diseases of the Liver*: Murchison, Habershon. This long list by no means includes all the works which may be selected from, but it will be seen that we by no means wish to imply that the student should have to consult one-fourth even of the above. It will be necessary for him to procure one text-book, and the following brief hints may guide him in his selection:—Each has its own peculiarities. That of Dr. Tanner may be mentioned the first, because it has been longest in the field, and also because it is fully sufficient for most purposes; it is eminently practical. The handbook of Dr. F. T. Roberts is, however, perhaps the most useful, and abounds in information supplied in a thoroughly systematic manner, although, from the very extensive range travelled over, the subject is necessarily condensed, and the book, therefore, no light reading. It is pre-eminently a student's book. The work of Dr. Bristowe is more original, and is valuable especially in its pathological portions, and in the admirable account given of diseases of the nervous system. Dr. Aitken's "Outlines" are also good. But for a work which is both pleasant in the reading and valuable for its suggestiveness, the text-book of Professor Niemeyer takes the front rank. Certainly no candidate for the higher examinations should fail to read this book, and to carefully study it, for although in some sections it hardly comes up to the standard of some English authorities, yet, as a whole, there is no work like it. Nor should Dr. Watson's famous book on the "Principles and Practice of Physic" be omitted, for many an hour may be passed both profitably and with pleasure in the perusal of these classical lectures. Those who intend taking high degrees, such as the M.D., should read much of the "System of Medicine" edited by Dr. Reynolds, and the time would not be wasted in the perusal also of several of Trousseau's admirable lectures on Clinical Medicine, translated by the Sydenham Society. Such candidates also would do well to

read the monographs of Dr. Murchison on Diseases of the Liver, or those on Diseases of the Kidney by Drs. W. Roberts, Grainger Stewart, or Dickinson; and also to consult Dr. Walshe's works on Diseases of the Lungs and Diseases of the Heart, or the lectures of Dr. Balfour on the last-named subject. On Continued Fevers, there is no work comparable to Dr. Murchison's treatise. On diseases of the nervous system there are the larger works of Rosenthal and Hammond; but the lectures of Dr. Wilks, and those of Charcot, some of which have been translated by the Sydenham Society, may profitably be read. Dr. Bastian's lectures on Brain Diseases and Dr. Gowers' lectures on Diseases of the Spinal Cord should prove of great use to the clinical student, for whose needs we may now mention some works that have been specially written for aid in bedside observation:—

Clinical Medicine: Finlayson, Fenwick, Tanner, Gee, Barclay, Da Costa. *Urine Analysis*: Legg, Tyson. *Ophthalmoscopy*: Browne, Jackson, Gowers, Clifford Allbutt. The handbook edited by Dr. Finlayson is very complete of its kind; Fenwick's work is smaller, but has been much in use, whilst the subject of "physical signs" in chest disease is admirably treated of in Gee's little manual of Auscultation and Percussion. As aids in the analysis of urine, Dr. Legg's and Dr. Tyson's works are excellent. We have added four works on Ophthalmology; the first is a guide to the use of the ophthalmoscope, which the beginner will find of great service; but the senior student will be repaid by studying the excellent work, which includes an atlas, by Dr. Gowers, or the book by Clifford Allbutt on the same subject. For reference: Liebreich's plates, or those of Jaeger, may be consulted.

Pathology.—Green, Payne, Wilks and Moxon, Rindfleisch, Cornil and Ranvier, Rokitsansky, Billroth, Paget, Virchow. The best to serve as an introduction to the subject is Dr. Green's little book, which has run through many editions. The second edition of Jones and Sieveking's "Pathological Anatomy," edited by Dr. Payne, might be read, although there is much matter in it hardly consonant with present advances in the subject. The text-book of Drs. Wilks and Moxon is valuable as a companion to the museum and dead-house; whilst for Pathological Histology, for more advanced students, the work of Rindfleisch (Syd. Soc.), and to those who read French, that of MM. Cornil and Ranvier, may be recommended. An American translation of this work has recently appeared, and has been carefully edited by Mr. Shakespeare. Billroth's *Surgical Pathology* is well worthy of study, and those who can afford the time will be repaid by reading Sir James Paget's well-known work on *Surgical Pathology*. Virchow's little *Guide to Post-mortem Examinations* is of use as giving full directions for the careful pursuit of this part of pathology. The excellent analysis of the contents of St. Bartholomew's Hospital Museum, published by Mr. Walsham under the title of a "Manual of Surgical Pathology," contains in a concise form the leading facts of this subject; and it might profitably be used as a companion in other museums than the one for which it is especially intended.

Surgery.—Druitt, Bryant, Holmes; Erichsen, Gross, Holmes's System. *Practical*: Hill, Heath, Stimson, Bell and Maunder; Fergusson, Spence, Pirrie, Syme. The two text-books by Mr. Bryant and Mr. Holmes respectively are perhaps now the most widely read. Druitt's "Vademecum" is now less sought after; still, by some it may be preferred to either Bryant or Holmes. Of larger works Erichsen's "Science and Art of Surgery," or Gross' surgery, need only to be mentioned. Their merits are well and widely known. And the same may be said of Holmes's System of Surgery. Practical Surgery has been treated by Sir W. Fergusson, Mr. Spence, Dr. Pirrie, and Mr. Syme, in books which have obtained a deserved repute. The works of Bell, Maunder and Stimson, on Operative Surgery, and Mr. Heath's *Atlas*, are all excellent. Mr. Hill's book on Bandaging and Mr. Heath's on Minor Surgery are of great use to the student in his career as dresser or house-surgeon.

Midwifery.—Swayne, Meadows, Lloyd Roberts; Playfair, Leishman, Barnes, Clay. *Diseases of Women*: Lombe Atthill, Galabin, Barnes, Graily Hewitt, Thomas. In the department of *Midwifery* the best works are those of Playfair and Leishman, and Dr. Robert Barnes' or Mr. Clay's works on "Obstetric Operations." With these the student preparing for University degrees would be well armed; whilst for emergencies Dr. Swayne's "Obstetric Aphorisms for Students" is excellent, and may be used in conjunction with the lectures attended by the student. In *Gynaecology*

the small book of Dr. Lombe Atthill is deservedly popular. Of like scope is the handbook by Dr. Galabin. More extensive information may be found in the larger works of Drs. Barnes, Graily Hewitt, and Thomas.

Dermatology.—Liveing's Diagnosis, Fox's Epitome, Duh-ring, Malcolm Morris; Tilbury Fox, Neumann (Pillar's translation.) *Atlases:* Tilbury Fox, Duhring. The student will find ample information within a small compass in the first-named works. Duhring's book is not so well known in this country as it deserves to be, and Neumann's is especially rich in cutaneous pathology.

Diseases of the Eye.—Nettleship, Lawson, Macnamara, Soelberg Wells. The most useful for the student are the two first named.

Diseases of the Ear.—Allen, Dalby, Keene, Field, Hinton, Woakes.

Dental Anatomy and Surgery.—C. Tomes, J. Tomes, Salter, Harris.

Medical Electricity.—De Watteville, Reynolds, Poore.

Hygiene.—Wilson, Parkes, De Chaumont, Teale.

We need but enumerate the authors in the above subjects; and we have only to add one subject which is still included in the University of London curriculum for candidates for the M.D. degree:

Logic and Moral Philosophy.—Bain and Jevons are the authors most generally read; but those who can make the acquaintance of Mill, Lewes, and Spencer will not regret it.

PRELIMINARY EDUCATION.

To the Editor of THE LANCET.

SIR,—After carefully reading your article in THE LANCET of August 28th, dealing with Dr. Karl Hillebrand's view on the advantages to be derived from a classical education by the medical student, and having mentally given my complete acquiescence to the views therein contained, I was not a little surprised, as well as rather amused, to find a letter by Dr. J. Niven in the same journal a few pages farther on, inasmuch as I found it to contain views so utterly and diametrically opposed to those I had just been perusing.

Now, I certainly am of opinion that it would be advisable for the intending medical student to have some sort of *practical* acquaintance with chemistry, physiology, and botany prior to the commencement of his professional studies; indeed, I think these subjects should be included in the scheme of the preliminary examinations, *but not rendered compulsory*, and for the reason asserted by Dr. Hillebrand, that there is such a tendency in the present age to learn too many facts, to read too many books. For a knowledge of a profession holding such a position as that of medicine, it is essential that a large mass of facts and details should be committed to memory; but do we not, in the first place, require a mind capable of appreciating those facts—a mind which, from its previous training and the culture thence derived, has been rendered capable of suitably marshalling those facts, of appreciating them duly, and of distinguishing between such as are useful and such as are comparatively useless for the purpose in hand? Now, Dr. Niven admits the study of the French and German languages to be useful, not as a mental training in the first place—no, he utterly ignores that very great advantage derived from the study of a language,—but to enable a man to read foreign authors and glean from them more facts. It is well known, and few, I think, would be rash enough to gainsay the statement nowadays, that as a means of mental training, as a means tending above measure to refine a man's manner and elevate his intellectual faculties, a good classical substratum is of the highest benefit and importance. With regard to so many medical and scientific terms being derived from the languages of ancient Greece and Rome, I think I need make no remark.

Call the acquirement of the classics, as some do with a sneer, a "mere accomplishment" even, but let us bear this in mind, that medicine owes its position as a learned profession to the accomplishments of those who adorn its ranks, and it is as well to bear in mind this little piece of history, to wit, the fact that Linnæus was not only the first founder of a College of Medicine, but the first who gave lectures in Greek at Oxford and Cambridge, and that great and renowned scholar Erasmus asserted that the best scholars of

his age—a golden age of classical scholarship—were the physicians of England.

The unravelling the particular meaning connoted by a particular word used in a particular sentence, the comparison of its meaning as employed there with that of its meaning as employed elsewhere, the investigation of the laws governing the construction of some abstruse grammatical sentence, the inquiry into the subtlety of meaning of the Greek particles, in a word, the logical skill, the nicety thus acquired will, in my opinion, prove of the very greatest benefit to the medical man, who has nearly every day to call these qualities into action.

A man entering upon the study of medicine should certainly avoid the "useless toil" (for useless toil *this* most assuredly is) of acquiring "a smattering of Latin and Greek," to quote Dr. Niven's own words, and I would call to his attention that *even in the syntax* of any good Latin grammar, abounding as it does in quotations from the "auctores classici," "elegance of address and refinements of speech and thought" (*sic*) cannot but "entangle themselves." Again, why should the intending medical student necessarily read the *Anabasis* of Xenophon? Would it not be more beneficial for him to peruse the second book of the history of Thucydides, or some one of the philosophical works of Plato?

But what a great benefit is to be derived from the classical languages in enabling us to more clearly understand our own—to appreciate Milton, for example—and that this is a *sine quâ non* to a medical man who can deny? The study of the classics has always been acknowledged to be *γενναίου ἀνδρός*, enabling men to express their thoughts clearly and accurately, and giving them the power of methodising and illustrating. Is it to be imagined that these great men "on fame's eternal bead-roll worthy to be filed," were ignorant of the language in which were couched those elegant compliments on their respective merits, when in the Senate House at Cambridge the other day they were invested with the honorary degree of LL.D.? I fancy not.

"Ordinis hæc virtus erit et venus, aut ego fallor,
Ut jam nunc dicat, jam debentia dici,
Pleraque differat et præsens in tempus omittat."

The gift of saying at the right time and the right place, and of doing at the right opportunity, that which should be said and done may be learned from the study of the ancient classics. It is by those, too, who have had a good substratum of Greek and Latin scholarship that the *modern languages* are more easily acquired, and this is, I think, admitted by most people of the present time. In conclusion I would ask these two questions, appending the answers:—
Q. In what language did Hippocrates write? A. In the purest Ionic Greek.

Q. Who was Hippocrates? A. The father of physio.

The conclusion is obvious.

I am, Sir, yours obediently,
WILLIAM A. GORDON LAING, M.B., C.M., &c.

SESSION 1880-81.

GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION OF THE UNITED KINGDOM.

Registration of Medical Students.—The following regulations have been adopted by the General Medical Council in reference to the registration of students in medicine:—Every medical student shall be registered in the manner prescribed by the General Medical Council. No medical student shall be registered until he has passed a preliminary examination as required by the General Medical Council, and has produced evidence that he has commenced medical study. The commencement of the course of professional study recognised by any of the qualifying bodies shall not be reckoned as dating earlier than fifteen days before the date of registration. The registration of medical students shall be placed under the charge of the branch registrars. Each of the branch registrars shall keep a register of medical students according to a prescribed form, wherein is set forth the name, the preliminary examination and date thereof, the date of registration, and the place and date of commencement of medical study, as certified by a master or a teacher, or an official in a medical school or hospital. Every person

desirous of being registered as a medical student shall apply to the branch registrar of the division of the United Kingdom in which he is residing; and shall produce or forward to the branch registrar a certificate of his having passed a preliminary examination as required by the General Medical Council, and evidence that he has commenced medical study. The branch registrar shall enter the applicant's name and other particulars in the Students' Register, and shall give him a certificate of such registration. Each of the branch registrars shall supply to the several qualifying bodies, medical schools, and hospitals, in that part of the United Kingdom of which he is registrar, a sufficient number of blank forms of application for the registration of medical students. The several Branch Councils have power to admit special exceptions to the foregoing regulations as to registration, for reasons which shall appear to them satisfactory. A copy of the Register of Medical Students, prepared by each of the branch registrars, shall be transmitted on or before Dec. 31st, in each year, to the registrar of the General Council, who shall, as soon as possible thereafter, prepare and print, under the direction of the Executive Committee, an alphabetical list of all students registered in the preceding year, and supply copies of such authorised list to each of the bodies enumerated in Schedule A to the Medical Acts, and through the branch registrars to the several medical schools and hospitals. The several qualifying bodies are recommended not to admit to the final examination for a qualification under the Medical Acts any candidate (not exempted from registration) whose name has not been entered in the Medical Students' Register at least forty-five months previously. In the case of candidates from other than schools of the United Kingdom, the Branch Councils have power to admit exceptions to this recommendation.

Pursuant to a resolution passed by the General Council at its meeting on July 14th, 1880, the changes made by the Council in its Regulations for Preliminary General Education, will from January 1st, 1882, be as follows:—On and after the first day of January, 1882, no person shall be allowed to be registered as a medical student unless he shall have previously passed a Preliminary Examination in the subjects of General Education as specified in the following list:—(1) English Language, including Grammar and Composition;¹ (2) English History; (3) Modern Geography; (4) Latin, including Translation from the original and Grammar; (5) Elements of Mathematics, comprising (a) Arithmetic, including Vulgar and Decimal Fractions; (b) Algebra, including simple Equations; (c) Geometry, including the first two books of Euclid or the subjects thereof; (6) Elementary Mechanics of Solids and Fluids, comprising the Elements of Statics, Dynamics, and Hydrostatics;² (7) One of the following optional subjects:—(a) Greek; (b) French; (c) German; (d) Italian; (e) any other Modern Language; (f) Logic; (g) Botany; (h) Elementary Chemistry.

Communications relating to the Medical Students' Register, or to the registration of medical students, should be sent to the registrars as follows:—W. J. C. Miller, B.A., Registrar of the General Council, 315, Oxford-street, London, W.—Archibald Inglis, M.D., Registrar of the Branch Council for Scotland, 33, Albany-street, Edinburgh.—W. E. Steele, M.D., Registrar of the Branch Council for Ireland, 35, Dawson-street, Dublin.

REGULATIONS OF THE MEDICAL EXAMINING BOARDS IN THE UNITED KINGDOM.

UNIVERSITY OF OXFORD.

Every student must reside in one or other of the Colleges or Halls, or in licensed lodgings, for three years, passing at least two examinations in Arts, and one in either Mathematics, Natural Science, Law, Modern History, or Theology,

¹ The General Medical Council will not consider any Examination in the English Language sufficient that does not fully test the ability of the candidate:—(1) To write sentences in correct English on a given theme, attention being paid to spelling and punctuation as well as to composition; (2) to write correctly from dictation; (3) to explain the grammatical construction of sentences; (4) to point out the grammatical errors in sentences ungrammatically composed, and to explain their nature; and (5) to give the derivation and definition of English words in common use.

² This subject may be passed either as Preliminary, or before, or at the first Professional Examination.

when, if he obtain a first, second, or third class, he can take his B.A. degree; if he do not gain such honour, he has to pass a third examination in *Literis Humanioribus*.

A student desiring to graduate in Medicine must pass the requisite examinations for the degree of B.A. He must afterwards spend two years in study³ prior to the first or scientific examination for the degree of Bachelor of Medicine, and two years more, after passing the first, prior to the final or practical examination for the same degree. Evidence must be brought to show that he has studied the practical parts of his profession in a first-class hospital.

There is an examination in State Medicine and Public Health, to which Bachelors of Medicine of the University are admissible. Copies of the examination-papers in the several examinations may be obtained through any bookseller.

A dissertation has to be publicly read, three years after obtaining the M.B., before being eligible for the M.D.

The study of Natural Science is carried on at the Museum, in which are extensive opportunities for the study of Physics, Chemistry, General, Comparative, and Human Anatomy, Histology, and other departments of Natural Science, together with courses of lectures and of practical instruction by the several professors. Collections illustrate the various subjects. There is in the medical department a pathological series, including the collection of Schroeder Van der Kolk, and a sanitary laboratory, conducted by the public analyst. The Radcliffe Library, containing above 25,000 scientific volumes, is open to all students daily from 10 till 4, and on certain evenings during term. There are lectures and practical instruction in Botany at the Botanical Gardens, and clinical instruction at the Infirmary.

The medical examinations take place this year in the Michaelmas term; after which, in the Trinity (summer) term, scholarships of about the value of £75 are obtainable at Christ Church, Magdalen, and other colleges, by competitive examination in Natural Science. Every year a Radcliffe Travelling Fellowship is competed for by any who, having taken a first class in any of the schools, or having obtained a University prize or scholarship, propose to study Medicine. The Travelling Fellows receive £200 a year for three years, half this period being spent in study abroad.

More detailed information may be obtained from the University Calendar; from the Student's Handbook to the University; from the Regius Professor of Medicine; from the Professors in the several departments; from E. Chapman, Esq., M.A., Frewin Hall; and from the Sub-Librarian in the Radcliffe Library at the Museum.

Regius Professor of Medicine—H. W. Acland, M.D., LL.D., F.R.S.
Professor of Geometry—H. S. Smith, M.A., F.R.S.
Professor of Natural Philosophy—Rev. B. Price, M.A., F.R.S.
Professor of Experimental Physics—S. Clifton, M.A., F.R.S.
Linacre Professor of Physiology—G. Rolleston, M.D., F.R.S.
Professor of Chemistry—W. Odling, M.A., F.R.S.
Professor of Zoology—J. O. Westwood, M.A., F.R.S.
Professor of Geology—J. Prestwich, M.A., F.R.S.
Professor of Botany—M. Lawson, M.A.
Professor of Mineralogy—N. S. Maskelyne, M.A., F.R.S.
Lee's Reader in Anatomy—J. B. Thompson, B.A.
Lee's Reader in Physics, Christ Ch.—R. E. Baynes, M.A.
Lee's Reader in Chemistry, Christ Ch.—A. G. V. Harcourt, M.A.
Lecturer in Natural Science, Exeter Coll.—W. L. Morgan, B.A.
Lecturer in Natural Science, Balliol—W. W. Fisher, M.A.
Millard Lecturer in Physics, Trinity—A. Macdonell, B.A.
Lecturers in Natural Science, Magdalen—E. Chapman, M.A., and C. J. F. Yule, M.A.
Lecturer in Natural Science, St. John's—W. H. Jackson, M.A.
Lecturer in Physical Science, Jesus—E. Chapman, M.A.
Lecturer in Natural Science, Keble—E. B. Poulton, M.A.
Demonstrator in Anatomy—Charles Robertson, Esq.
Demonstrator in Chemistry—W. W. Fisher, M.A.
Public Analyst in Sanitary Laboratory—W. F. Donkin, M.A.

UNIVERSITY OF CAMBRIDGE.

The student must enter at one of the Colleges, or as a non-collegiate student, and keep terms for three years by residence in the University. He must pass the Previous Examination in Classics and Mathematics, which may be done, and should if possible be done, in the first or second term of residence, or, through the Oxford and Cambridge Schools Examination Board or the Local Examinations, before commencing residence. He may then devote himself to medical study in the University, attending the hospital and the medical lectures, dissecting, &c. Or he may proceed to take a degree in Arts, either continuing mathematical and

³ If he have taken the higher honours in the Natural Science School he may go in for the first M.B. examination on the first opportunity, and so have a longer period of practical study before the second M.B. examination.

classical study, and passing the ordinary examinations for B.A., or going out in one of the Honour Triposes. The Natural Science Tripos is preferred by most medical students, some of the subjects for this Tripos examination (Chemistry, Botany, Human and Comparative Anatomy, and Physiology) forming part of the series of medical study.

The expenses of residence, lectures, &c., at a college are about £150 per annum; but these are in many cases lessened by scholarships, ranging in value from £20 to £80 a year, which are very numerous, and obtainable by most students of industry and ability. They are chiefly given for mathematical and classical proficiency. Some may be obtained at once, even before entering; and notices of the examinations for these are given from time to time under the head of "University Intelligence" in *The Times* and other newspapers. Scholarships are given for Natural Science in Trinity, St. John's, St. Peter's, Clare, Christ's, Sydney, Pembroke, Caius, and Downing Colleges; the examinations being at Easter, also in June and October.⁴

Non-collegiate students can reside at less expense (£80 or £90 a year) than those who enter a College. They are allowed to attend certain of the College lectures and all the professors' lectures, and have the same University status and privileges as the other students. They are under the superintendence of the Rev. R. B. Somerset, Oxford House, Cambridge, from whom further information may be obtained. Cavendish College has been recently founded, to afford special facilities for obtaining a degree at a moderate cost, and at the earliest practicable age. Information may be obtained from J. Cox, Esq., warden of the College.

For the degree of *Bachelor in Medicine* five years of medical study are required, except in the case of medical students who have graduated with honours as Bachelors of Arts, four years being then sufficient. This time may be spent in Cambridge or elsewhere. The earlier portion of it is usually spent in Cambridge, the student remaining in the University till he has passed the examination for the Natural Sciences Tripos and the first and second examinations for M.B.

There are three examinations for M.B. The *first* in Chemistry and other branches of Physics, and Botany. The *second* in Anatomy and Physiology (Human and Comparative), and Pharmacology. The *third* (at the conclusion of medical study) in Medicine, Surgery, Midwifery, and Medical Jurisprudence. The examinations are partly in writing and partly oral, in the hospital, in the dissecting-room, and in the laboratories. They take place twice annually (in June and December).

An Act has to be kept, which consists in reading an original thesis and passing a *viva voce* examination on the subject of the thesis and on other subjects.

Previously to the first examination, lectures must have been attended on Chemistry (with manipulations) and Botany. Previously to the second examination, the student must have attended lectures on Human Anatomy and Physiology, Comparative Anatomy, *Materia Medica* and Pharmacy, and Pathology; have Dissected one season; and attended Hospital Practice one year. Previously to the third examination, lectures must have been attended on Pathological Anatomy, the Principles and Practice of Physic, Clinical Medicine, Clinical Surgery, Midwifery (with ten cases), and Medical Jurisprudence; also Hospital Practice for three years. The candidate must also have been a clinical clerk, or have had special charge of patients in a hospital, dispensary, or parochial union for six months.

The degree of *Doctor in Medicine* may be taken three years after M.B. An Act has to be kept, with *viva voce* examination; and an extempore essay has to be written on some subject relating to Physiology, Pathology, the Practice of Medicine, or State Medicine. A Master of Arts proceeding to M.D. is required to produce the same certificates and pass the same examinations as for M.B.

For the degree of *Master in Surgery* the candidate must have passed the three examinations for M.B., and have attended lectures on Human Anatomy (a second course), on the Principles and Practice of Surgery, Clinical Surgery; he must have dissected a second season, have attended the Surgical Practice at a recognised hospital for three years, and have held a house-surgeoncy or dressership for six months. He is then required to pass an examination in

Surgical Anatomy, Pathology, and the Principles and Practice of Surgery, and Clinical Surgery.

The next examination in Sanitary Science by the University of Cambridge will begin on Oct. 5th. Candidates (whose names must be on the Medical Register of the United Kingdom) should send their names to Professor Living, Cambridge, before Sept. 25th.

The following is a summary of the course which a student (commencing at the University, say, in October, 1880) may follow:—He enters at any one of the colleges, or as a non-collegiate student, and passes the Previous Examination (in Classics and Mathematics), in October, 1880, or in April, 1881, unless he has already passed the equivalent examination under the Oxford and Cambridge Schools Examination Board. He is then registered as a student of medicine. Medical study in the University for two years. Natural Sciences Tripos examination (in Human and Comparative Anatomy, Chemistry, and Botany), in June, 1883; this admits to B.A. degree in June, 1883. Second examination for M.B. (in Human Anatomy and Physiology, and *Materia Medica*), December, 1883, or May, 1884. Third examination for M.B. (in Medicine, Surgery, Midwifery, and Medical Jurisprudence), November, 1885; Examination for M.C. (in Surgical Anatomy, Pathology, and Surgery), November, 1885. Degree of M.B. or M.C., November, 1884. Part of the period of medical study is thus spent in Cambridge, and part (say after the second examination) in London or elsewhere.

Attendance at the hospital and on the lectures on Anatomy, Chemistry, &c., is recognised by the Universities of Cambridge and London, and by the College of Surgeons.

The students should remain in Cambridge during part of the long vacation (July and August) and part of the Christmas vacation, as well as during the terms.

UNIVERSITY OF LONDON.

The *Matriculation Examinations* take place on January 14th, and June 21st, 1881. The fee for the examination is £2. Provincial examinations are appointed by the Senate from time to time at specified centres. Several scholarships, exhibitions, and prizes are associated with these examinations.

The *Preliminary Scientific (M.B.) Examination* takes place once in each year, and commences on the third Monday in July.⁵ No candidate will be admitted to this examination until he shall have completed his seventeenth year, and shall have either passed the Matriculation Examination or taken a degree in Arts in one of the Universities of Sydney, Melbourne, Calcutta, or Madras (provided that Latin was one of the subjects in which he passed); nor unless he have given notice of his intention to the registrar at least fourteen days before the commencement of the examination. Fee for this examination £5.

Candidates are examined on the following subjects:—Inorganic Chemistry, Experimental Physics, Botany, and Vegetable Physiology, and Zoology. The examiners will publish a list of the candidates who have passed, arranged in two divisions, each in alphabetical order. And a pass certificate signed by the registrar will be delivered to each candidate who shall apply for it, after the report of the examiners shall have been approved by the Senate.

Any candidate who has passed the Preliminary Scientific (M.B.) Examination may be examined at the Honours Examination next following the Preliminary Scientific Examination at which he has passed for honours in (1) Experimental Physics, (2) Chemistry, (3) Botany, (4) Zoology, unless he have previously obtained an exhibition in any one of these subjects at the First B.Sc. Examination, in which case he shall not be admissible to the examination for honours in that subject.

Bachelor of Medicine.—Every candidate for the degree of Bachelor of Medicine will be required—1. To have passed the Matriculation Examination in this University (unless he has taken a degree in Arts in one of the Universities of Sydney, Melbourne, Calcutta, or Madras, and Latin was one of the subjects in which he passed). 2. To have passed the Preliminary Scientific Examination. 3. To have been engaged in

⁴ For an account of these Scholarships see THE LANCET of April 12th, 1882; and for an account of the Scholarships for Natural Sciences see *Nature* in the early part of each year. Further information may be obtained from the *Student's Handbook to the University*, published by Messrs. Deighton, Cambridge, price 1s. 6d.

⁵ Candidates for the Degree of M.B. are strongly recommended by the Senate to pass the Preliminary Scientific Examination before commencing their regular medical studies, and to devote a preliminary year to preparation for it according to the following programme:—Winter Session: Experimental Physics, Chemistry (especially Inorganic), Zoology. Summer Session: Practical Chemistry (Inorganic), Botany.

his professional studies during four years subsequently to matriculation or graduation in Arts at one or more of the medical institutions or schools recognised by this University, one year at least of the four to have been spent in one or more of the recognised institutions or schools in the United Kingdom. 4. To pass two examinations in Medicine.

First M.B. Examination.—The First M.B. Examination takes place once in each year, and commences on the last Monday in July. No candidate shall be admitted to this examination unless he have passed the Preliminary Scientific Examination at least one year previously, and have produced certificates to the following effect:—1. Of having completed his nineteenth year. 2. Of having, subsequently to having passed the Matriculation Examination, or taken a degree in Arts in one of the before-named universities, been a student during two years at one or more of the medical institutions or schools recognised by this University, and of having attended a course of lectures on each of three of the subjects in the following list:—Descriptive and Surgical Anatomy, Histology and Physiology, Pathological Anatomy, Materia Medica and Pharmacy, General Pathology, General Therapeutics, Forensic Medicine, Hygiene, Obstetric Medicine and Diseases peculiar to Women and Infants, Surgery, Medicine. 3. Of having, subsequently to having passed the Matriculation Examination, or taken a degree in Arts, Dissected during two winter sessions. 4. Of having, subsequently to having passed the Matriculation Examination or taken a degree in Arts, attended a course of Practical Chemistry, comprehending practical exercises in conducting the more important processes of General and Pharmaceutical Chemistry; in applying tests for discovering the adulteration of articles of the Materia Medica, and the presence and nature of poisons; and in the examination of mineral waters, animal secretions, urinary deposits, calculi, &c. 5. Of having attended to Practical Pharmacy, and of having acquired a practical knowledge of the preparation of medicines. These certificates (as is the case also with all the certificates hereinafter mentioned) must be transmitted to the registrar at least fourteen days before the commencement of examination. Fee for this examination, £5.

Candidates will be examined in the following subjects: Anatomy, Histology and Physiology, Materia Medica and Pharmaceutical Chemistry, Organic Chemistry. Candidates will not be approved by the examiners unless they have shown a competent knowledge in all these subjects.

Any candidate who has passed the First M.B. Examination may be examined, at the Honours Examination next following the First M.B. Examination at which he passed, for Honours in (1) Anatomy, (2) Materia Medica and Pharmaceutical Chemistry, (3) Physiology and Histology, and (4) Organic Chemistry. The examinations take place in the week following that in which the Pass Examination commenced. They are conducted by means of printed papers and practical work.

If, in the opinion of the examiners, sufficient merit be evinced, the candidate who shall distinguish himself the most in Anatomy, and the candidate who shall distinguish himself the most in Histology and Physiology, will each receive an exhibition of £40 per annum for the next two years; the candidate who shall distinguish himself the most in Organic Chemistry, and the candidate who shall distinguish himself the most in Materia Medica and Pharmaceutical Chemistry, will each receive an exhibition of £30 per annum for the next two years. On receiving each quarterly instalment he must declare his intention of presenting himself at the Second M.B. Examination within three academical years from the time of his passing the First M.B. Examination. Under the same circumstances, the first and second candidates in Anatomy and in Histology and Physiology, and the first candidate in Organic Chemistry and in Materia Medica and Pharmaceutical Chemistry, will each receive a gold medal of the value of £5.

*Second M.B. Examination.*⁶—The Second M.B. Examination takes place once in each year, and commences on the first Monday in November. Each candidate, after two academical years passing the First Examination, must produce certificates to the following effect:—1. Of having

passed the First M.B. Examination. 2. Of having, subsequently to having passed the First M.B. Examination, attended a course of lectures on each of two of the subjects enumerated in section 2 of the regulations for that examination, and for which the candidate had not on that occasion presented certificates. 3. Of having conducted at least twenty labours. Certificates on this subject will be received from any legally qualified practitioner in medicine. 4. Of having attended the Surgical Practice of a recognised hospital or hospitals during two years, with clinical instruction and lectures on Clinical Surgery. 5. Of having attended the Medical Practice of a recognised hospital or hospitals during two years, with clinical instruction and lectures on Clinical Medicine. 6. Of having, after having attended Surgical and Medical Hospital Practice for at least twelve months subsequently to passing the First M.B. Examination, attended to Practical Medicine, Surgery, or Obstetric Medicine, with special charge of patients, in a hospital, infirmary, dispensary, or parochial union, during six months, such attendance not to be counted as part of either the Surgical or the Medical Hospital Practice prescribed in Clauses 4 and 5. 7. Of having acquired proficiency in Vaccination. Certificates on this subject will be received only from the authorised vaccinators appointed by the Privy Council. The candidate must also produce a certificate of moral character from a teacher in the last school or institution at which he has studied, as far as the teacher's opportunity of knowledge has extended. The fee for this examination is £5.

Candidates will be examined in the following subjects:—General Pathology, General Therapeutics and Hygiene, Surgery, Medicine, Obstetric Medicine, Forensic Medicine. The examinations will include questions in Surgical and Medical Anatomy, Pathological Anatomy, and Pathological Chemistry. Candidates will not be approved by the examiners unless they have shown a competent knowledge in all the subjects of examination.

Any candidate who has passed the Second M.B. Examination may be examined at the Honours Examination next following the Second M.B. Examination at which he has passed, for Honours in (1) Medicine, (2) Obstetric Medicine, and (3) Forensic Medicine. The examinations commence in the week following that in which the Pass Examination terminated. Except in the case of Forensic Medicine they are conducted by means of printed papers, but the examiners will not be precluded from putting *viva voce* questions upon the written answers of the candidates when they appear to require explanation.

If, in the opinion of the examiners, sufficient merit be evinced, the candidate who shall distinguish himself the most in Medicine will receive £50 per annum for the next two years, with the style of University Scholar in Medicine. Under the same circumstances the candidate who shall distinguish himself the most in Obstetric Medicine will receive £30 per annum for the next two years, with the style of University Scholar in Obstetric Medicine. Under the same circumstances, the candidate who shall distinguish himself the most in Forensic Medicine will receive £30 per annum for the next two years, with the style of University Scholar in Forensic Medicine. Under the same circumstances the first and second candidates in each of the preceding subjects will each receive a gold medal of the value of £5.

Bachelor of Surgery.—The examination for the degree of Bachelor of Surgery takes place once in each year, and commences on the Tuesday following the fourth Monday in November. Candidates must produce certificates to the following effect:—1. Of having passed the Second Examination for the degree of Bachelor of Medicine in this University. 2. Of having attended a course of instruction in Operative Surgery, and of having operated on the dead subject. Fee for this examination, £5.

Any candidate who has passed the B.S. Examination may be examined at the Honours Examination next following the B.S. Examination at which he has passed, for Honours in Surgery. The examination takes place on Tuesday in the week following the Pass Examination, and is conducted by means of printed papers. If in the opinion of the examiners sufficient merit be evinced, the candidate who shall distinguish himself the most will receive £50 per annum for the next two years, with the style of University Scholar in Surgery. Under the same circumstances, the first and second candidates will each receive a gold medal of the value of £5.

Master in Surgery.—The examination for the degree of

⁶ Any candidate for the Second M.B. Examination who has passed the First M.B. Examination under the former regulations, will be required to have also passed the examination in Physiology at some previous First M.B. Examination carried on under the present regulations, at which examination he shall not be allowed to compete for Honours.

Master in Surgery takes place once in each year, and commences on the fourth Monday in November.

Candidates must produce certificates to the following effect:—1. Of having taken the degree of Bachelor of Surgery in this University. (Candidates who have obtained the degree of Bachelor of Medicine previously to 1866 will be admitted to the examination for the degree of Master in Surgery without having taken the degree of Bachelor of Surgery; and in the case of such candidates the attendance on surgical practice required by regulation 2 may commence from the date of the M.B. degree.) 2. Of having attended, subsequently to having taken the degree of Bachelor of Surgery in this University. (a) To Clinical or Practical Surgery during two years in a hospital or medical institution recognised by this University. (b) Or to Clinical or Practical Surgery during one year in a hospital or medical institution recognised by this University, and of having been engaged during three years in the practice of his profession. (c) Or of having been engaged during five years in the practice of his profession, either before or after taking the degree of Bachelor of Surgery in this University. One year of attendance on Clinical or Practical Surgery, or two years of practice, will be dispensed with in the case of those candidates who at the B.S. Examination have been placed in the first division. 3. Of moral character, signed by two persons of respectability. Fee for this degree, £5. The examination is conducted by means of printed papers and *viva voce* interrogation.

Candidates will be examined in Logic and Psychology, and Surgery, and will not be approved unless they have shown a competent knowledge in both the subjects of examination.

If sufficient merit be evinced, the candidate who shall distinguish himself the most in Surgery at this examination will receive a gold medal of the value of £20.

Doctor of Medicine.—The examination for this degree takes place once in each year, and commences on the fourth Monday in November.

Candidates must produce certificates to the following effect:—1. Of having passed the Second Examination for the degree of Bachelor of Medicine in this University. 2. Of having attended, subsequently to having taken the degree of Bachelor of Medicine in this University, (a) to Clinical or Practical Medicine during two years in a hospital or medical institution recognised by this University; or (b) to Clinical or Practical Medicine during one year in a hospital or medical institution recognised by this University, and of having been engaged during three years in the practice of his profession. (c) Or of having been engaged during five years in the practice of his profession, either before or after taking the degree of Bachelor of Medicine in this University. One year of attendance on Clinical or Practical Medicine or two years of practice will be dispensed with in the case of those candidates who at the Second M.B. Examination have been placed in the first division. 3. Of moral character, signed by two persons of respectability. The fee for this degree is £5. The examination is conducted by means of printed papers and *viva voce* interrogation.

Candidates will be examined in Logic and Psychology, and Medicine, and will not be approved unless they have shown a competent knowledge in both the subjects of examination. If sufficient merit be evinced, the candidate who shall distinguish himself the most in Medicine at the examination for the M.D. degree will receive a gold medal of the value of £20.

Public Health.—A Special Examination will be held once in every year in subjects relating to Public Health, to commence on the Second Monday in December. Candidates must have passed the Second Examination for the B.M. degree in this University at least one year previously; and must give notice of their intention to the Registrar at least *two calendar months* before the commencement of the examination. The fee for this examination is £5. Candidates will be examined in Chemistry and Microscopy, Meteorology, Geology, Physics and Sanitary Apparatus, Vital Statistics, Hygiene, and Sanitary Law. The examination will be both written and practical, and will extend over four days. Candidates will not be approved unless they have shown a competent knowledge in all the principal subjects of the examination. If sufficient merit be evinced, the candidate who shall distinguish himself the most shall receive a gold medal of the value of £5.

A certificate under the seal of the University, and signed by the Chancellor, will be delivered at the public presentation for degrees to each candidate who has passed.

UNIVERSITY OF DURHAM.

There are two licences and three degrees conferred—viz., a licence in Medicine and a licence in Surgery; and the degrees of Bachelor of Medicine, Master in Surgery, and Doctor of Medicine. A certificate of proficiency in Sanitary Science is also awarded.

For the degree of *Bachelor in Medicine* there are two professional examinations; the first being held twice yearly—viz., in October (in 1880 commencing on the 4th) and April (in 1881 commencing on the 25th); the second twice yearly—viz., in December (in 1880 commencing on the 6th) and in June (in 1881 commencing on the 13th).

The subjects for the first examination are—Anatomy, Physiology, Chemistry, and Botany. Candidates must produce the following certificates:—(1) Of registration as a medical student. (2) Of having passed one of the following examinations in Arts: (a) the examination for graduation in Arts at one of the following universities—Oxford, Cambridge, Durham, Dublin, London, Queen's (Ireland), Edinburgh, Glasgow, St. Andrews, Aberdeen, Calcutta, Madras, Bombay, McGill College (Montreal), and Queen's College (Kingston); or (b) the Preliminary or Extra-professional examination for graduation in Medicine at one of the following universities—London, Edinburgh, Glasgow, St. Andrews, Aberdeen, and Queen's (Ireland); or (c) the Preliminary Examination in Arts qualifying for the membership of the Royal College of Physicians of London or for the fellowship of the Royal College of Surgeons of England. Candidates who, at the commencement of their professional education, passed the Arts examination for registration only, may pass in the extra subjects required for the M.B. Durham either before or after presenting themselves for the first examination for the degree, but must do so before presenting themselves for the final examination. (3) Of attendance on two courses of Anatomy, on one of Physiology, on one of Theoretical and one of Practical Chemistry, and on one of Botany; of twelve months' dissection; and of attendance on a course of Practical Physiology of not less than thirty lessons.

The subjects for the Second Examination are Medicine, Surgery, and Public Health, Pathology, Materia Medica, Therapeutics, Midwifery and Diseases of Women and Children, and Medical Jurisprudence. For it candidates must produce the following certificates—viz., (1) of being not less than twenty-one years of age; (2) of good moral character; and (3) of attendance on the remainder of the course of medical and surgical study as prescribed by the Royal College of Surgeons of England, together with the following additional subjects—viz., one course of lectures on Medicine, one on Therapeutics, one on Public Health, and one on Botany and on Medical Hospital Practice, with Clinical Lectures during one winter and one summer session. There must be proof that the whole course of professional study has occupied at least four years.

N.B.—It is required that one of the four years of professional education shall be spent in attendance at the College of Medicine, Newcastle-upon-Tyne. During the year so spent the candidate must attend at least two courses of lectures in the winter session and two in the summer session, together with the class and test examinations held in connexion with those classes, and must also attend hospital practice and clinical lectures at the infirmary during the same period. Candidates may fulfil this portion of the curriculum at any period before they present themselves for the Final Examination for the degree, but are strongly recommended to do so previously to the First Examination. They are not required to reside at Durham. The other three years of the curriculum may be spent either at Newcastle-upon-Tyne or at one or more of the schools recognised by the licensing bodies named in Schedule A of the Medical Act, 1858. Candidates who are already qualified by other of the licensing bodies are required to attend for one winter and one summer session at the College of Medicine, Newcastle-upon-Tyne, in the manner indicated in the preceding paragraph.

For the degree of *Master in Surgery* the candidate must have passed the Examination for the Degree of Bachelor in Medicine and must have attended one course of lectures on Operative Surgery. Each candidate will have an additional

paper on Surgery, and will have to perform operations on the dead body and to explain the use of instruments.

For the degree of *Doctor of Medicine* candidates must be not less than twenty-four years of age, must have obtained the degree of M.B. at least two years previously, and in the interim have been engaged in medical or surgical practice. Each candidate will be required to write an essay on some medical subject selected by himself and approved by the Professor of Medicine, and to pass an examination thereon, and must be prepared to answer questions on the other subjects of his curriculum in so far as they are related to the subject of his essay.

Candidates for any of the above degrees must give at least twenty-eight days' notice to the Registrar of the College, sending at the same time the fee and the necessary certificates.

The Degree of Doctor of Medicine, for Medical Practitioners of fifteen years' standing, without residence.—The Warden and Senate of the University of Durham, with the view of affording to practitioners of fifteen years' standing an opportunity of obtaining the degree of Doctor of Medicine, have instituted a Special Examination, under the following regulations:—1. That the candidate shall be registered by the General Council of Medical Education and Registration of the United Kingdom. 2. That the candidate shall have been in the active practice of his profession for fifteen years as a qualified practitioner. 3. That the candidate shall not be under forty years of age. 4. That the candidate shall produce a certificate of moral character from three registered members of the medical profession. 5. That if the candidate shall not have passed, previous to his Professional Examination (in virtue of which he has been placed on the Register), an examination in Arts, he shall be required to pass an examination in Classics and Mathematics. The subjects for this examination shall be as follows: (1) An English Essay (a short essay on some subject to be specified at the time of the examination). (2) Arithmetic. (3) Euclid—books i. and ii. (4) Latin—Translation from Virgil, *Æneid*, books i. and ii., together with grammatical questions. (5) One of the following subjects: *a*, Greek—Translation from Xenophon's *Memorabilia*, books i. and ii., with grammatical questions; *b*, French—Translation from Voltaire's *Charles XII.*, with grammatical questions; *c*, German—Translation from Goethe's *Dichtung und Wahrheit*, book i., with grammatical questions; *d*, Elements of Mechanics, Pneumatics, and Hydrostatics; *e*, some Treatise on Moral, Political, or Metaphysical Philosophy. 6. That if the candidate shall have passed, previous to his Professional Examination (in virtue of which he has been placed on the Register), a preliminary examination, he shall be required to translate into English passages in any of the parts specified below of any one of the Latin authors mentioned: *Cæsar*—*De Bello Gallico*, first three books; *Virgil*—first three books of the *Æneid*; *Celsus*—first three books. (The candidate may choose for himself any one of these three authors on whose works he is to be examined.) The candidate shall have an opportunity of showing proficiency in Greek, Moral Philosophy, or some modern language. 7. That the candidate shall pass an examination in the following subjects: *a*, Principles and Practice of Medicine, including Psychological Medicine, and Hygiene; *b*, Principles and Practice of Surgery; *c*, Midwifery and Diseases peculiar to Women and Children; *d*, Pathology, Medical and Surgical; *e*, Anatomy, Medical and Surgical; *f*, Medical Jurisprudence and Toxicology; *g*, Therapeutics. 8. That the fee shall be 50 guineas. 9. That if the candidate shall fail to satisfy the examiners, the sum of 20 guineas shall be retained; but that, if he shall again offer himself for the examination, the sum of 40 guineas only shall then be required.

Examinations in accordance with the above regulations will commence on Dec. 6th, 1880, and June 13th, 1881, in the College of Medicine, Newcastle-on-Tyne. Gentlemen intending to offer themselves as candidates are requested to forward their names to Dr. Luke Armstrong, registrar of the University of Durham College of Medicine, Newcastle-on-Tyne, on or before Nov. 1st, 1880, or May 1st, 1881, together with the fee and the before-mentioned certificates.

Certificate of Proficiency in Sanitary Science.—Candidates for this certificate must be registered medical practitioners and have attended one course of lectures on Public Health, at the College of Medicine, Newcastle-on-Tyne, extending over one winter session. They shall be required to pass an examination on the following subjects:—Physics: Laws of light, heat, hydro-dynamics, and pneumatics. Chemistry:

As applied to the detection of noxious gases, and atmospheric impurities, analysis of air and water. Sanitary Legislation: Knowledge of the Acts of Parliament in force for the preservation and protection of health. Vital Statistics: Rates of births, deaths, and marriages; methods of calculation, classification, and tabulation, of returns of sickness and mortality; data and conclusions deducible therefrom. Meteorology; Climatology, and Geographical Distribution of Diseases in the United Kingdom. Sanitary Medicine, more especially in relation to epidemic, endemic, epizootic, and communicable diseases; diseases attributable to heat, cold, or damp; insufficiency or impurity of air, food, or drink; habitation, occupation, over-exertion, intemperance, heredity. Preventive Measures: Vaccination, isolation, disinfection; the regulation of noxious and offensive manufactures and trades; the removal of nuisances. Practical Hygiene, in reference to site, materials, construction, lighting, ventilation, warmth, dryness, water-supply, and refuse disposal of dwellings, schools, hospitals, and other buildings of public and private resort; action with respect to nuisances and outbreaks of disease; other duties of a Medical Officer of Health.—The examination will be by written papers, practical and *viva voce*, and will commence on October 4th, 1880, and on April 25th, 1881. In the practical examination, the candidate will be required:—To report upon the condition of some actual locality, to analyse liquids and gases, to explain the construction and use of instruments employed in meteorology, and to make microscopic examinations. The fee is £5 5s.

Candidates for the Certificate of Proficiency in Sanitary Science, who shall have been Medical Officers of Health of five years' standing, and members of the profession who have obtained a registrable qualification before January 1st, 1878, must be registered medical practitioners, and be not under thirty years of age. They will be required to pass the same examination as before mentioned, write an essay upon some practical sanitary subject, and will be examined upon the essay, and upon other sanitary questions. The fee is £10 10s. During the ensuing year two examinations will be held, commencing the one on October 4th, 1880, the other on April 25th, 1881.

UNIVERSITY OF EDINBURGH.

The session 1880–81 will be opened on October 26th.

Three medical degrees are conferred by the University of Edinburgh—namely, Bachelor of Medicine (M.B.), Master in Surgery (C.M.), and Doctor of Medicine (M.D.). The degree of Master in Surgery is not conferred on any person who does not also at the same time obtain the degree of Bachelor of Medicine. All candidates for these degrees must give evidence of having obtained a satisfactory general education.

1. The preliminary branches of extra-professional education are English, Latin, Arithmetic, the Elements of Mathematics, and the Elements of Mechanics; and the proficiency of students in these branches is ascertained by examination prior to the commencement of their medical study.

2. No candidate is admitted to a professional examination who has not passed a satisfactory examination on at least two of the following subjects (in addition to the subjects mentioned above):—Greek, French, German, Higher Mathematics, Natural Philosophy, Logic, Moral Philosophy; and the examination on these latter subjects also takes place before the candidate has entered on his medical curriculum.

3. A degree in Arts (not being an honorary degree) in any one of the universities of England, Scotland, or Ireland, or in any foreign or colonial university specially recognised for this purpose by the University Court, exempts from all preliminary examination; and an examination in Arts by any corporate body, whose examination has been recognised as qualifying for entrance on medical study by resolution of the General Medical Council of the United Kingdom, provided the said examination by the said corporate body shall also be approved by the University Court, shall exempt *pro tanto* from preliminary examination in Arts, on the subjects comprised in the examination of the said corporate body.

4. No one is admitted to the degree of Bachelor of Medicine or Master in Surgery who has not been engaged in medical and surgical study for four years—the medical session of each year, or *annus medicus*, being constituted by at least two courses of not less than one hundred lectures each, or by one such course and two courses of not less than fifty lectures each; with the exception of the clinical courses,

in which lectures are to be given at least twice a week during the prescribed periods.

5. Every candidate for the degrees of M.B. and C.M. must give sufficient evidence by certificates—1. That he has studied each of the following departments of medical science—namely, Anatomy, Chemistry, Materia Medica, Institutes of Medicine or Physiology, Practice of Medicine, Surgery, Midwifery and the Diseases peculiar to Women and Children, and General Pathology, each during courses including not less than one hundred lectures; Practical Anatomy, a course of the same duration as those of not less than one hundred lectures; Practical Chemistry, three months; Practical Midwifery, three months at a midwifery hospital, or a certificate of attendance on six cases from a registered medical practitioner; Clinical Medicine, Clinical Surgery,⁷ courses of the same duration as those of not less than one hundred lectures, or two courses of three months' lectures, being given at least twice a week; Medical Jurisprudence, Botany, Natural History (including Zoology), during courses including not less than fifty lectures. 2. That he has attended, for at least two years, the medical and surgical practice of a general hospital which accommodates not fewer than eighty patients, and possesses a distinct staff of physicians and surgeons. 3. That he has been engaged, for at least three months, by apprenticeship or otherwise, in compounding and dispensing drugs at the laboratory of a hospital, dispensary, member of a surgical college or faculty. Licentiate of the London or Dublin Society of Apothecaries, or member of the Pharmaceutical Society of Great Britain. 4. That he has attended, for at least six months, by apprenticeship or otherwise, the out-practice of a hospital, or the practice of a dispensary, physician, surgeon, or member of the London or Dublin Society of Apothecaries.

6. Students of Medicine in the London schools, and in the school of the College of Surgeons in Dublin, can obtain three *anni medici* out of the four required for the Edinburgh degrees in Medicine. One *annus medicus* may be constituted by attendance on Practical Anatomy and Hospital Practice during the winter session. Another *annus medicus* by attending either (a) full winter courses on any two of the following subjects:—Anatomy, Physiology, Chemistry, Pathology, Surgery, Medicine, Clinical Surgery, Clinical Medicine; or (b) on one such course and three months' courses on any two of the following subjects:—Botany, Practical Chemistry, Natural History, Medical Jurisprudence. If the student selects the arrangement prescribed in (a), certificates of attendance on either a third winter course, or a third three months' course, will also be accepted by this University. The other subjects, and the additional courses, not given in London or Dublin, required for the degrees of the University, will have to be attended at this University. In provincial schools, where there are no lecturers recognised by the University Court, a candidate can only have one *annus medicus*, and this is constituted by attendance on a qualified hospital along with a course of Practical Anatomy. All candidates not students of the University; availing themselves of the permission to attend the lectures of extra-academical teachers in Edinburgh must, at the commencement of each year of such attendance, enrol their names in a book to be kept by the University for that purpose, paying a fee of the same amount as the matriculation fee paid by students of the University, and having, in respect of such payment, a right to the use of the library of the University. The fee for attendance on the lectures of an extra-academical teacher in Edinburgh, with a view to graduation, must be of the same amount as that exigible by medical professors in the University. No teacher is recognised who is at the same time a teacher of more than one of the prescribed branches of study, except in those cases where professors in the University are at liberty to teach two branches. It is not necessary for any teacher, attendance on whose lectures is now recognised for the purpose of graduation in the University, to obtain a new recognition from the University Court; and attendance on the lectures of every such teacher will continue to be recognised as heretofore. It is in the power of the University Court, if they shall see cause, at any time to withdraw or suspend the recognition of any teacher or teachers.

7. Every candidate must deliver, before the 31st day of March of the year in which he proposes to graduate, to the Dean of the Faculty of Medicine, a declaration, in his own

handwriting, that he has completed his twenty-first year, or that he will have done so on or before the day of graduation, and that he will not be, on the day of graduation, under articles of apprenticeship to any surgeon or other master; together with a statement of his studies, as well in Literature and Philosophy as in Medicine, accompanied with proper certificates.

8. Each candidate is examined, both in writing and orally, on Chemistry, Botany, and Natural History; on Anatomy, Institutes of Medicine, Materia Medica (including Practical Pharmacy), and Pathology; on Surgery, Practice of Medicine, Midwifery, and Medical Jurisprudence; clinically on Medicine and on Surgery in a hospital. The examinations on Anatomy, Chemistry, Institutes of Medicine, Botany, Natural History, Materia Medica, and Pathology are conducted, as far as possible, by demonstrations of objects placed before the candidates.

9. Students who profess themselves ready to submit to an examination on the first division of these subjects, at the end of their second year, may be admitted to examination at that time. Provided always that students who commence their medical studies in the summer session, and who profess themselves ready to submit to an examination on the first division of these subjects at the beginning of their second winter session may be admitted to examination at that time on condition that they produce certificates of attendance on at least two classes during each of two summer sessions and one winter session; and on the further condition that they shall not be admitted to a degree in Medicine unless their course of study, subsequent to the completion of the summer session in which they commence their medical studies, shall not be less than the minimum course of four years prescribed in Section 4 hereof.

10. Students who have passed their examination on the first division of these subjects may be admitted to examination on the second division at the end of their third year.

11. The examination on the third and fourth divisions cannot take place until the candidate has completed his fourth *annus medicus*.

12. Candidates may, if they choose, be admitted to examination on the first two of these divisions at the end of their third year, or to the four examinations at the end of their fourth year.

13. If any candidate at these examinations be found unqualified, he cannot be again admitted to examination unless he has studied during another year two of the prescribed subjects, either in the University or in some other school of medicine.

14. After the candidate has satisfied the medical examiners, the Dean will lay the proceedings before the Senatus Academicus, by whose authority the candidate will be admitted on the first day of August, or if that day be Sunday, then on the following day, to the degree of M.B., or to the degrees of M.B. and of C.M.

15. The degree of Doctor of Medicine may be conferred on any candidate who has obtained the degree of Bachelor of Medicine, and who is of the age of twenty-four years, and produced a certificate of having been engaged, subsequently to his having received the degree of M.B. for at least two years in attendance on a hospital, or in the military or naval medical services, or in medical and surgical practice; provided always that the degree of M.D. shall not be conferred on any person, unless he be a graduate in Arts of one of the universities of England, Scotland, or Ireland, or of such other universities as are above specified, or unless he shall, before or at the time of his obtaining the degree of M.B., or thereafter, have passed a satisfactory examination on three of the subjects mentioned in Section II. of the statutes relative to preliminary examination. Two of these must be Greek, and Logic or Moral Philosophy, and the third is to be one of the following subjects, at the option of the candidate—namely, French, German, higher Mathematics, and Natural Philosophy, and provided also that the candidate for the degree of M.D. shall submit to the Medical Faculty a thesis, certified by him to have been composed by himself, and which shall be approved by the Faculty on any branch of knowledge comprised in the professional examinations for the degree of M.B., which he may have made a subject of study after having received that degree. The candidate must lodge his thesis with the Dean on or before 30th April of the year in which he proposes to graduate. No thesis will be approved by the Medical Faculty which does not contain either the results of original observations

⁷ The Medical Faculty recommend that medical students should not attend Clinical Surgery during their first six months' attendance on Clinical Medicine.

in practical medicine, surgery, midwifery, or in some of the sciences embraced in the curriculum for the Bachelor's degree; or else a full digest and critical exposition of the opinions and researches of others on the subject selected by the candidate, accompanied by precise references to the publications quoted, so that due verification may be facilitated.

16. Persons who began their medical studies before the 4th of February, 1861, are entitled to graduate under the system in force before or after that date, according as they may comply with the regulations in force in the University before or after that date.

The Preliminary Examinations in General Education are held in the Upper Library Hall, and students matriculated for the academic year are admitted on presenting their matriculation tickets at the door. Students matriculated for the summer only and non-matriculated students pay a fee of 10s. each, and are admitted on showing their receipts. Those who pay the fee in March will be admitted to the examination in October without further payment. Payment in October does not exempt from payment in March. The academic year is reckoned from 1st of November to 1st of November. Examinations on the preliminary branches of extra-professional education will take place on the 5th, 6th, 7th, and 8th October, 1880; and on the 15th, 16th, 17th, and 18th March, 1881.

The fees for M.B. £15 15s. Total fees and stamp for graduating as M.D. only, by regulations for students commencing before February, 1861, £25. The fees for examination must be paid at the secretary's office ten days before the dates thereof, and the fees for the degrees of C.M. and M.D., and the stamp-duty for the latter, must be paid on or before the 15th day of July in the year of graduation. In the event of the candidate not passing any one of the professional examinations, the fee is not returned; but he may appear at one subsequent examination without paying an extra fee, and at any future examination on paying one-half the fee.

The new buildings for the accommodation of the classes in the Medical Faculty of the University have made such progress during the past twelve months that the portion intended for the department of Anatomy will be ready for occupation at the commencement of the ensuing winter session. The departments of Pathology, Physiology, Practice of Physic, Midwifery, and Chemistry are nearly completed, and the remaining portions are in a forward state of preparation.

UNIVERSITY OF GLASGOW.

Three degrees in Medicine are granted—viz., Bachelor of Medicine, Master in Surgery, and Doctor of Medicine. The curricula of study and the examinations for the several degrees conferred are nearly the same as in the University of Edinburgh. The annual term for conferring medical and surgical degrees is the 1st of August. The Preliminary Examinations of medical students in branches of general education take place on the 6th of October, 1880, and on the 31st of March, 1881.

The fees for the degrees are the same as in the University of Edinburgh.

The regulations under which the above degrees are granted and the notices of the subjects of examination may be obtained by application to the assistant clerk of Senate of the University.

Bursaries tenable by Medical Students.—Two James Ferguson Bursaries, value £70 per annum each, tenable for two years by medical students who have attended certain prescribed courses in the Arts Faculty. The Brisbane Bursary, of £50 yearly, held for four years by a student of medicine who is a Master of Arts. The Walton Bursary, of £36 yearly, held by a medical student (a native of England being preferred) for four years. The Logan Bursary, of £16 yearly, tenable by a medical student for four years. Two Rainy Bursaries, value £20 per annum each, open to medical students who have just completed the second year of professional study, and tenable for two years. The Armagh Bursaries, three in number, amounting each to £25 yearly, for three years, open to students of Divinity, Law, and Medicine, who have taken the degree of M.A. The Macfarlane Bursary, value £40 per annum, and tenable for three years, open to students who have attended the first session of their professional study in the University of Glasgow, and who have passed in all the seven subjects of the Preliminary Examination for M.B. The Marshall Bursary,

value £17 per annum, and tenable for four years, open to students entering the Medical Faculty, and awarded by competition on the subjects of the Preliminary Examination. The Lorimer Bursary, value £50 per annum, tenable by a medical student for three years.

UNIVERSITY OF ABERDEEN.

The curricula for the several degrees conferred are nearly the same as in the University of Edinburgh.

Professional Examinations will be held twice in each year—namely, in April and July, directly after the close of the winter and summer sessions.

The fees for graduation are the same as in the University of Edinburgh. Matriculation fee, including all dues, for the winter and summer sessions, £1; summer session alone, 10s.

Candidates who commenced their medical studies before November, 1861, are entitled to appear for examination for the degree of M.D. after four years' study, one of which must have been in the University of Aberdeen.

Besides the Royal Infirmary, students who have the opportunity of attending the following institutions:—General Dispensary, and Lying-in and Vaccine Institutions, daily; Royal Lunatic Asylum; Eye Institution, in which is given clinical instruction on the Diseases of the Eye, and on the Application of the Ophthalmoscope for their diagnosis.

Application for further information should be addressed to Professor Brazier, Secretary to the Medical Faculty.

UNIVERSITY OF ST. ANDREWS.

Three degrees in Medicine are granted—namely, Bachelor of Medicine (M.B.), Master in Surgery (C.M.), and Doctor of Medicine (M.D.). The curricula for these degrees, and the regulations under which they are conferred, differ from those of the University of Edinburgh only in the particulars noticed below.

The degree of *Doctor of Medicine* may be conferred by the University of St. Andrews on any registered medical practitioner above the age of forty years whose professional position and experience are such as, in the estimation of the University, to entitle him to that degree, and who shall, on examination, satisfy the medical examiners of the sufficiency of his professional knowledge; provided always that degrees will not be conferred, under this section, to a greater number than ten in any one year. The examinations are held yearly, towards the end of April. Candidates must lodge with the Dean of the Medical Faculty the following certificates, along with application for admission to examination:—1. A certificate of age, being a baptismal certificate or an affidavit of age. 2. Holograph certificates from at least three medical men of acknowledged reputation in the medical profession or in the medical schools, recommending the candidate to the Senatus for the degree, and testifying to his professional skill and position. As only ten can graduate yearly, candidates will be selected whose service and certificates seem to the Medical Faculty to present the highest professional claims, and where these seem equal preference will be given to age and priority of application. 3. Candidates, when notified for examination, shall remit a portion of the graduation fee (viz., £10 10s.) This sum shall be forfeited should the candidate fail to appear, or to graduate, at the time appointed. 4. A satisfactory examination, written and *visd voce*, must be passed in the following departments—viz., *Materia Medica* and *General Therapeutics*, *Medical Jurisprudence*, *Practice of Medicine* and *Pathology*, *Surgery*, *Midwifery* and *Diseases of Women and Children*.

No one will be received as a candidate for the degree of *Bachelor of Medicine* or *Master in Surgery* unless two years at least of his four years of medical and surgical study shall have been in one or more of the following universities or colleges—viz., the Universities of St. Andrews, Glasgow, Aberdeen, Edinburgh, Oxford, and Cambridge; Trinity College, Dublin; Queen's College, Belfast; Queen's College, Cork; and Queen's College, Galway.

Subject always to the condition here specified, the studies for candidates for the degrees of Bachelor of Medicine and Master in Surgery will be under the following regulations: The remaining years of medical and surgical study may be either in one or more of the universities and colleges above specified, or in the hospital schools of London, or in the school of the College of Surgeons of Dublin, or under such private teachers of medicine as may from time to time receive recognition from the University Court. Attendance

during at least six winter months on the medical or surgical practice of a general hospital which accommodates at least eighty patients, and during the same period on a course of Practical Anatomy may be reckoned as one of such remaining years. Attendance on the lectures of any private teacher in Edinburgh, Glasgow, or Aberdeen will not be reckoned for graduation in St. Andrews, if the fee for such lectures be of less amount than is charged for the like course of lectures in the University of Edinburgh, of Glasgow, or of Aberdeen, according as the teacher lectures in those places respectively.

Every candidate for examination for the degrees of M.B. and C.M. is required to lodge a declaration of age, a statement of his course of study, his inaugural dissertation, and all his certificates, with the Dean of the Medical Faculty, on or before the 25th of March in each year.

No candidate offering himself for examination on the first two divisions of the subjects specified in Clause 12 of the regulations will be considered to have passed in the second if he fails in the first; and no candidate offering himself for examination on the three divisions shall be considered to have passed in the third if he fails either in the first or second division. Every candidate who fails to pass in any of the divisions will, for a first failure in any and each of the divisions, forfeit the sum of £2 2s., and £1 1s. for every subsequent failure in each.

UNIVERSITY OF DUBLIN (TRINITY COLLEGE).

Matriculation.—All students in the School of Physic intending to practise Physic must be matriculated, for which a fee of 5s. is payable. No student can be admitted for the winter course after Nov. 25th.

Previous Medical Examination.—Candidates for degrees and licences in Medicine and Surgery are required to pass a previous examination in Physics, Chemistry, Botany, Materia Medica and Pharmacy, and Descriptive Anatomy, and Institutes of Medicine (Practical Histology and Physiology) previous to their degree examination.

Bachelor in Medicine.—A candidate for this degree must be a graduate in Arts, and may obtain the degree of Bachelor in Medicine at the same commencement as that at which he receives his degree of B.A., or at any subsequent commencement. The medical education of a Bachelor in Medicine is of four years' duration, and comprises attendance on a single course of each of the following lectures:—Anatomy, Practical Anatomy, Surgery, Chemistry, Materia Medica and Pharmacy, Institutes of Medicine, Practice of Medicine, Midwifery, Botany, Medical Jurisprudence, Heat, Electricity, Magnetism, Comparative Anatomy. Three courses of nine months' attendance on the clinical lectures of Sir Patrick Dun's or other metropolitan hospital recognised by the Board of Trinity College. Six months' instruction in Practical Midwifery, including Clinical Lectures. A certificate of personal attendance on Fever cases, with names and dates of cases. Six months' dissections are required. Three months' laboratory instruction in Chemistry is required. Any of the above-named courses may be attended at any medical school in Dublin recognised by the Provost and senior Fellows. Fee for the *Licent ad Examinandum*, £5; for the M.B. degree £11.

Doctor in Medicine.—A Doctor in Medicine must be M.B. of at least three years' standing, or have been qualified to take the degree of M.B. for three years, and must perform exercises for the degree before the Regius Professor of Physic, in accordance with the rules and statutes of the University. Total amount of fees for this degree, £13.

Bachelor in Surgery.—A Bachelor in Surgery must be a Bachelor in Arts and in Medicine, and have spent four years in the study of Surgery and Anatomy. He must also pass a public examination in the Hall before the Professors of the School of Physic, having previously completed the prescribed curriculum of study.⁸ Candidates are required to perform surgical operations on the dead subject. Fee for the *Licent ad Examinandum*, £5; for the degree of Bachelor in Surgery, £5.

Master in Surgery.⁹—A Master in Surgery must be a Bachelor in Surgery of three years' standing, or have been qualified to take the degree of Bachelor in Surgery for three

years; and must read a thesis publicly before the Regius Professor of Surgery, or undergo an examination before the Regius Professor, according to regulations to be approved by the Provost and senior Fellows. Fee for the degree of Master in Surgery, £11.

University Licences.—Candidates for the Licences in Medicine or Surgery must be matriculated in Medicine, and must have completed two years in Arts and four years in medical studies.

Licentiate in Medicine.—The medical course and examination necessary for the Licence in Medicine are the same as for the degree of M.B. A Licentiate in Medicine, on completing his course in Arts, and proceeding to the degree of B.A., may become a Bachelor in Medicine, on paying the degree fees, without further examination in Medicine. Fee for the *Licent ad Examinandum*, £5; for the Licence in Medicine, £5.

Licentiate in Surgery.—The surgical course and examination necessary for the Licence in Surgery are the same as for the degree of Bachelor in Surgery. Fee for the *Licent ad Examinandum*, £5; for the Licence in Surgery, £5.

Medical Scholarships.—Two Medical Scholarships will be given annually, tenable for two years, with a salary of £20 per annum, on the conditions stated in the University Calendar.

Qualification in State Medicine.—Doctors in Medicine or graduates in Medicine and Surgery of Dublin, Oxford, or Cambridge, who wish to obtain from the University a Certificate of Qualification in State Medicine, can do so on passing an examination in a limited course of the following subjects:—1. Law, comprehending sanitary legislation, and the laws relating to the conduct and duties of medical men. 2. Engineering in its sanitary aspects. 3. Pathology, including the laws of epidemics, vaccination, insanity, &c. 4. Vital and sanitary statistics. 5. Chemistry in relation to air, water, gaseous poisons, deodorisation, and disinfection. 6. Meteorology. 7. Medical Jurisprudence.

The total cost of the education and first degrees in Medicine and Surgery is as follows, in addition to the fees for education in Arts and B.A. degree (£83 4s.); Medical and Surgical Lectures, £59 1s.; Hospitals, £42 2s.; Medical and Surgical Examinations and Degrees, £31.

THE QUEEN'S UNIVERSITY IN IRELAND.

Students who wish to obtain the degree of M.D., or of M.Ch., in the Queen's University must be matriculated students of one of the Queen's Colleges—Belfast, Cork, and Galway—and must pursue the courses of study prescribed by the Senate of the University.

Medical students may matriculate either at the General Matriculation Examination on October 19th, 1880, or at the Supplementary Examination held in the second or third week of November.

Each candidate for the degree of *Doctor in Medicine* or *Master in Surgery* is required (1) to have passed in one of the Colleges of the Queen's University the Entrance Examination in Arts, and to have been admitted a matriculated student of the University; (2) to have attended in one of the Queen's Colleges lectures on one modern continental language for six months, and lectures on Natural Philosophy for six months; (3) to have also attended, in some one of the Queen's Colleges, at least two of the courses of lectures marked with an asterisk. For the remainder of the courses authenticated certificates will be received from the professors or lecturers in universities, colleges, or schools recognised by the Senate of the Queen's University in Ireland; (4) to pass three University Examinations—the First University Examination, the Second University Examination, and the Degree Examination.

The curriculum extends over at least four years, and is divided into periods of at least two years each. Candidates are recommended to pass the Matriculation Examination prior to entering on the second period. It is recommended that the first period shall comprise attendance on the following courses of medical lectures: *Chemistry; *Botany, with herborisations for practical study, and Zoology; *Anatomy and Physiology; *Practical Anatomy; *Materia Medica and Pharmacy. And that the second period shall comprise attendance on the following courses of medical lectures: Anatomy and Physiology (second course); Practical Anatomy (second course); *Theory and Practice of Surgery; *Midwifery; *Theory and Practice of Medicine; *Medical Jurisprudence. In addition to the above courses of lectures candidates shall have

⁸ Students in the School of Physic who matriculated before June 22nd, 1872, may obtain the degree of Master in Surgery according to the regulations in force previous to the creation of the degree of Bachelor in Surgery.

⁹ Masters in Surgery must be of the standing of Masters of Arts.

attended, during either the first or second period: A Modern Continental Language (in one of the Colleges of the University; Experimental Physics (in one of the Colleges of the University). Also, during the first period: Practical Chemistry (in a recognised laboratory); Medico-Chirurgical Hospital (recognised by the Senate) containing at least sixty beds, together with the Clinical Lectures therein delivered, at least two each week—a winter session of six months. And during the second period: Practical Midwifery—a certificate of having attended at a recognised midwifery hospital, with the Clinical Lectures therein delivered, for a period of three months, or of having attended a midwifery dispensary for the same period, or of having attended ten cases of labour under the superintendence of the medical officer of any hospital or dispensary where cases of labour are treated; Medico-Chirurgical Hospital (recognised by the Senate) containing at least sixty beds, together with the Clinical Lectures therein delivered, eighteen months—including either three winter sessions of six months each, or two winter sessions of six months each and two summer sessions of three months each.

Medical examinations are held in June, and in September and October. The June examinations are Pass Examinations. Those held in September and October include both Honour and Pass Examinations. Each candidate for examination in June must forward to the Secretary, on or before the 20th of May, notice of his intention to offer himself as a candidate, along with his certificates; and each candidate for examination in September and October must forward similar notice, along with his certificates, before the 20th of August.

A candidate who has been rejected at the examination for the degree of M.D., will not be allowed to present himself for re-examination within six months, unless by special grace of the Senate.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

The licence of this College is a qualification to practise Medicine, Surgery, and Midwifery, and is recognised by the Poor-law Board as a qualification in Surgery as well as in Medicine.

Licentiate.—Every candidate for the College licence (except when otherwise provided by the bye-laws) is required to produce satisfactory evidence to the following effect:—Of having attained the age of twenty-one years. Of moral character. Of having passed before the commencement of professional study, an examination in the subjects of general education recognised by the General Medical Council. Of having been registered as a medical student in the manner prescribed by the General Medical Council. "Every candidate (not exempted from registration) is required to have been registered at least forty-five months previously to admission to the Final Examination." Of having been engaged in professional studies during at least forty-five months, of which at least three winter sessions and two summer sessions shall have been passed at a recognised medical school or schools, and one winter session and two summer sessions in one or other of the following ways:—

1. Attending the practice of a hospital or other institution recognised by the College for that purpose.
2. Receiving instruction as the pupil of a legally qualified practitioner having opportunities of imparting a practical knowledge of Medicine, Surgery, or Midwifery.
3. Attending lectures on any of the required subjects of professional study at a recognised place of instruction. Professional studies commenced before Registration, except in the subjects of the First Examination, will not be recognised by the College. Of having attended, during three winter sessions and two summer sessions, the medical and surgical practice at a recognised hospital or hospitals;¹⁰ of having discharged the duties of a medical clinical clerk during six months; and of surgical dresser during other months; and of having been engaged during six months in the clinical study of Diseases peculiar to Women. Of having received instruction in Chemistry, Practical Chemistry, Materia Medica, Botany, and Practical Pharmacy. Of having attended a course of lectures on the following subjects:—Anatomy (with Dissections), during twelve months; Physiology; a practical course of General Anatomy during a winter or a summer

session, consisting of not less than thirty meetings of the class; Pathological Anatomy; Principles and Practice of Medicine; Principles and Practice of Surgery; Midwifery and the Diseases peculiar to Women; Forensic Medicine. Of having attended Clinical Lectures on Medicine during nine months, and also Clinical Lectures on Surgery during nine months, and of having been engaged during a period of three months in the Clinical Study of Diseases peculiar to Women. Of having passed the professional examinations.

Any candidate who shall produce satisfactory evidence of having passed an examination on Anatomy and Physiology, conducted by a university in the United Kingdom, in India, or in a British colony, or by the College of Surgeons in England, Scotland or Ireland, or the Faculty of Physicians and Surgeons of Glasgow, shall be exempt from re-examination on those subjects. Any candidate who shall produce satisfactory evidence of having passed an examination on Chemistry and Materia Medica, required for a degree in Medicine at a university in the United Kingdom, in India, or in a British colony, will be exempted from re-examination on those subjects. Any candidate who shall have obtained a degree in Surgery at a university in the United Kingdom, after a course of study and an examination satisfactory to the College, shall be exempt from re-examination on Surgical Anatomy, and on the Principles and Practice of Surgery. Any candidate who shall have passed the examination on Surgery conducted by the Royal College of Surgeons of England, or the Royal College of Surgeons of Edinburgh, or the Royal College of Surgeons in Ireland, or the Faculty of Physicians and Surgeons of Glasgow, after a course of study and an examination satisfactory to the College, shall be exempt from re-examination on Surgical Anatomy, and on the Principles and Practice of Surgery. Any candidate, being a "registered medical practitioner," whose qualification or qualifications shall have been obtained before the first day of January, 1861, having been with the consent of the College admitted a candidate for the licence, will be examined on the Principles and Practice of Medicine, Surgery, and Midwifery; but he will be exempted from such other parts of the professional examinations as his qualifications may seem to the examiners to render in his case unnecessary. Any candidate who shall have obtained a foreign qualification which entitles him to practise Medicine or Surgery in the country where such qualification has been conferred, after a course of study and an examination equivalent to those required by the regulations of the College, shall, on production of satisfactory evidence as to age, moral character, and proficiency in vaccination, be admissible to the Pass Examination, and shall be exempt from re-examination on such subjects as shall in each case be considered by the Censors' Board to be unnecessary.

Examinations will take place in the months of February, April, July, October, and December.

Members.—The members of the College, present and future, shall be alone eligible to the fellowship. Every candidate (except such as are admissible under special provisions relating to practitioners) must produce proof of his having been engaged in professional studies during a period of five years, of which four years at least shall have been passed at a medical school or schools recognised by the College. Every candidate shall produce evidence, satisfactory to the Censors' Board, of his having studied the following subjects: Anatomy (with Dissections), during two winter sessions; Physiology, two winter sessions; Chemistry, six months; Practical Chemistry, three months; Materia Medica, three months; Practical Pharmacy, three months; Botany, three months; Morbid Anatomy, six months; Principles and Practice of Medicine, two winter sessions; Principles and Practice of Surgery, two winter sessions; Clinical Medicine, three winter and three summer sessions; Clinical Surgery, two winter and two summer sessions; Midwifery and the Diseases peculiar to Women, three months; Forensic Medicine, three months. He shall also give satisfactory proof of having attended diligently during three winter and three summer sessions the medical practice, and during three winter and two summer sessions the surgical practice, of a hospital containing at least a hundred beds; of having been engaged during six months in the clinical study of Diseases peculiar to Women; and of having served the office of clinical clerk in the medical wards during at least six months. If the Censors' Board doubt the sufficiency of the certificates produced by any candidate, or his fitness in any respect for admission to examination, they may submit the

¹⁰ A three months' course of clinical instruction in the wards of a recognised lunatic hospital or asylum may be substituted for the same period of attendance in the medical wards of a general hospital.

case to a general meeting of the fellows. No candidate shall be admitted to examination who is engaged in trade; or who dispenses medicine, or makes any engagement with a chemist or any other person for the supply of medicines; or who practises medicine or surgery, in partnership, by deed or otherwise, so long as that partnership continues. No candidate shall be admitted to examination who refuses to make known, when required by the president and censors, the nature and composition of any remedy he uses. Every candidate must give proof of his acquirements by written answers to questions placed before him, and shall be examined *vivâ voce* at three separate examinations, and shall be approved by the president and censors, or by the major part of them. Any candidate who shall produce satisfactory evidence of having passed an examination on Chemistry and Materia Medica, required for a degree in medicine at a university in the United Kingdom, in India, or in a British colony, will be exempted from re-examination on those subjects. Any candidate who has already obtained the degree of Doctor or Bachelor of Medicine at a university in the United Kingdom, in India, or in a British colony, or who shall have obtained a foreign qualification entitling him to practise medicine or surgery in the country where such qualification has been conferred, wherein the courses of study and the examinations to be undergone previous to graduation shall have been adjudged by the Censors' Board to be satisfactory, shall be exempt (if the censors shall think fit) from all or any parts of the examinations hereinbefore described, except such as relate to the Third or Pass Examination. The nature and extent of this examination shall, in the case of each candidate, be determined by the Censors' Board. Every candidate for the membership will, however, be required to translate into English a passage from a Latin author, and he will have the opportunity of showing a knowledge of Greek or of one or more of the modern European languages. Any candidate who shall produce satisfactory evidence of having passed an examination on Anatomy and Physiology, conducted by any of the bodies named in Schedule A to the Medical Act and recognised by the College as requiring a course of study and an examination satisfactory to the College, will be exempt from re-examination on the subjects of the Primary Examinations. Any candidate who shall have obtained a degree in Surgery, at a university in the United Kingdom, after a course of study and an examination satisfactory to the College, will be exempt from re-examination on Surgical Anatomy and the Principles and Practice of Surgery. Any candidate who shall have passed the examination on Surgery conducted by the Royal College of Surgeons of England, or the Royal College of Surgeons of Edinburgh, or the Royal College of Surgeons in Ireland, or the Faculty of Physicians and Surgeons of Glasgow, after a course of Study and an examination satisfactory to the College, will be exempt from re-examination on Surgical Anatomy and on the Principles and Practice of Surgery. Every candidate approved by the Censors' Board shall be proposed at the next general meeting of fellows, as qualified to become a member of the College; and if the majority of the fellows present shall consent, he shall, on complying with the regulations prescribed by the by-laws, be admitted a member of the College.

Examinations for the Membership will take place in the months of January, April, July, and October.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

REGULATIONS RESPECTING THE EDUCATION AND EXAMINATION OF CANDIDATES FOR THE DIPLOMA OF MEMBER.

Preliminary General Education and Examination.—Candidates who commenced their professional education on or after 1st January, 1861, will be required to produce one or other of the certificates of proficiency granted by the educational bodies specified in the recommendations of the General Medical Council. Candidates who shall not be able to produce one or other of those certificates will be required to pass an examination in English Classics, and Mathematics, conducted by the Board of Examiners of the Royal College of Preceptors, under the direction and supervision of this College.

N.B.—Each candidate, who has not at a previous examination paid the amount, is required to pay a fee of £2 on the morning of the first day of the examination prior to his admission thereto. Examinations are held in March

and September. Particulars respecting the examination will be duly advertised in the journals. Candidates are required to apply for the prescribed form of application a month before the date of the examination, and to send the same to the College not less than three weeks before its commencement.

Professional Education.—Professional Studies prior to the date at which the Candidate shall have passed an Examination in General Knowledge in conformity with the Regulation in the preceding Section are not recognised. The following will be considered as the commencement of Professional Education:—

(1) Attendance on the Practice of a Hospital, or other Public Institution recognised by this College for that purpose.

(2) Instruction as the Pupil of a legally qualified Surgeon, holding the appointment of Surgeon to a Hospital, General Dispensary, or Union Workhouse, or where such opportunities of practical instruction are afforded as shall be satisfactory to the Council.

(3) Attendance on Lectures on Anatomy, Physiology, or Chemistry, by Lecturers recognised by this College.

Candidates, prior to their admission to the First or Primary Examination on Anatomy and Physiology, will be required to produce the following certificates, viz.:—Of having passed, prior to the commencement of professional study, a recognised Preliminary Examination. Of having attended lectures on Anatomy during two winter sessions. Of having performed Dissections during not less than two winter sessions. Of having attended lectures on General Anatomy and Physiology during one winter session. Of having attended a Practical Course¹¹ of General Anatomy and Physiology during another winter or a summer session, consisting of not less than thirty meetings of the class. The Certificates of attendance on the several courses of lectures must include evidence that the Student has attended the Practical Instructions and Examinations of his teacher in each course.

Candidates, prior to their admission to the Second or Pass Examination on Surgical Anatomy and the Principles and Practice of Surgery and Medicine, will be required to produce the following certificates, viz.:—Of being twenty-one years of age. Of having been engaged, subsequently to the date of passing the Preliminary Examination, during four years, or during a period extending over not less than four winter and four summer sessions, in the acquirement of professional knowledge. Of having attended lectures on Surgery during one winter session. Of having attended a course of Practical Surgery¹² during a period occupying not less than six months prior or subsequent to the course required by the preceding clause. Of having attended one course of lectures on each of the following subjects—Chemistry,¹³ Materia Medica, Medicine, Forensic Medicine, Midwifery (with practical instruction, and a certificate of having personally conducted not less than ten labours), Pathological Anatomy during not less than three months. Of having studied Practical Pharmacy during three months. Of having attended a three months' course of Practical Chemistry (with manipulations) in its application to medical study. Of instruction and proficiency in the practice of Vaccination. Of having attended at a recognised hospital or hospitals the Practice of Surgery during three winter¹⁴ and two summer¹⁵ sessions. Of having been individually engaged, at least twice in each week, in the observation and examination of patients at a recognised hospital or hospitals, under the direction of a recognised

¹¹ By the Practical Course is meant that the learners themselves shall, individually, be engaged in the necessary experiments, manipulations, &c.; but it is not hereby intended that the learners shall perform vivisections.

¹² The course of Practical Surgery is intended to embrace instruction in which each pupil shall be exercised in practical details, such as in the application of anatomical facts to surgery, on the living person, or on the dead body. The methods of proceeding and the manipulations necessary in order to detect the effects of diseases and accidents, on the living person, or on the dead body. The performance, where practicable, of the operations of surgery on the dead body. The use of surgical apparatus. The examination of diseased structures, as illustrated in the contents of a museum of Morbid Anatomy and otherwise.

¹³ The course of lectures on Chemistry included will not be required in the case of a Candidate who shall have passed a satisfactory Examination in this subject in his Preliminary Examination.

¹⁴ The winter session comprises a period of six months, and, in England, commences on the 1st of October and terminates on the 31st of March.

¹⁵ The summer session comprises a period of three months, and, in England, commences on the 1st of May and terminates on the 31st of July.

teacher, during not less than three months. Of having, subsequently to the first winter session of attendance on Surgical Hospital Practice, attended, at a recognised hospital or hospitals, Clinical Lectures on Surgery, during two winter and two summer sessions. Of having been a Dresser at a recognised hospital, or of having, subsequently to the completion of one year's professional education, taken charge of patients under the superintendence of a surgeon during not less than six months, at a hospital, general dispensary, or parochial or union infirmary recognised for this purpose, or in such other similar manner as, in the opinion of the Council, shall afford sufficient opportunity for the acquirement of Practical Surgery. Of having attended, during the whole period of attendance on Surgical Hospital Practice, demonstrations in the post-mortem rooms of a recognised hospital. Of having attended at a recognised hospital or hospitals, the Practice of Medicine, and Clinical Lectures on Medicine, during one winter and one summer session.

Certificates will not be received on more than one branch of science from one and the same lecturer; but Anatomy and Dissections will be considered as one branch of science.

Certificates will not be recognised from any hospital or school of surgery in the United Kingdom unless the surgeons or teachers thereof be members of one of the legally constituted Colleges of Surgeons in the United Kingdom; nor from any School of Anatomy and Physiology or Midwifery, unless the teachers in such school be members of some legally constituted College of Physicians or Surgeons in the United Kingdom.

No metropolitan hospital will be recognised by this College which contains less than 150, and no provincial or colonial hospital which contains less than 100 patient. The recognition of colonial hospitals and schools is governed by the same regulations with respect to number of patients and to courses of lectures as apply to the recognition of provincial hospitals and schools in England.

Certificates of attendance upon the practice of a recognised provincial or colonial hospital unconnected with, or not in convenient proximity to, a recognised medical school, will not be received for more than one winter and one summer session of the hospital attendance required by the regulations of this College; and in such cases clinical lectures will not be necessary, but a certificate of having acted as dresser for at least six months will be required.

Those candidates who shall have pursued the whole of their studies in Scotland or Ireland will be admitted to examination upon the production of the several certificates required respectively by the College of Surgeons of Edinburgh, the Faculty of Physicians and Surgeons of Glasgow, and the College of Surgeons in Ireland, from candidates for their diploma, together with a certificate of instruction and proficiency in the practice of Vaccination, and satisfactory evidence of having been occupied, subsequently to the date of passing the Preliminary Examination, at least four years, or during a period extending over four winter and four summer sessions, in the acquirement of professional knowledge; and, in the case of candidates who shall have pursued the whole of their studies at recognised foreign or colonial universities, upon the production of the several certificates required for their degree by the authorities of such universities, together with a certificate of instruction and proficiency in the practice of Vaccination, and satisfactory evidence of having been occupied, subsequently to the date of passing the Preliminary Examination, at least four years, or during a period extending over four winter and four summer sessions, in the acquirement of professional knowledge.

Members or licentiates of any legally-constituted College of Surgeons in the United Kingdom, and graduates in Surgery of any university recognised for this purpose by this College, will be admitted to examination on producing their diploma, licence, or degree, together with proof of being twenty-one years of age, a certificate of instruction and proficiency in the practice of Vaccination, and satisfactory evidence of having been occupied, subsequently to the date of passing the Preliminary Examination, at least four years, or during a period extending over four winter and four summer sessions, in the acquirement of professional knowledge.

Graduates in Medicine of any legally-constituted college or university, recognised for this purpose by this College, will be admitted to examination on adducing, together with their diploma or degree, proof of being twenty-one years of age, a certificate of instruction and proficiency in the practice of Vaccination, and satisfactory evidence of having been occupied, subsequently to the date of passing the

Preliminary Examination, at least four years, or during a period extending over four winter and four summer sessions, in the acquirement of professional knowledge.

Professional Examination.—This examination is divided into two parts. The First or Primary Examination, on Anatomy and Physiology, is partly written and partly demonstrative on the recently dissected subject, and on prepared parts of the human body. The Second or Pass Examination, on Surgical Anatomy and the Principles and Practice of Surgery and Medicine,¹⁶ is partly written, partly oral, and partly on the practical use of surgical apparatus and the practical examination of patients. The Primary Examinations are held in the months of January, April, May, July, and November, and the Pass Examinations generally in the ensuing week respectively.

Candidates will not be admitted to the Primary Examination until after the termination of the second winter session of their attendance at a recognised school or schools, nor to the Pass or Surgical Examination until after the termination of the fourth year of their professional education.

The fee of £5 5s., paid prior to the first admission to the Primary Examination, is retained whether the candidates pass or fail to pass the examination, but is allowed as part of the whole fee of £22¹⁷ payable for the diploma. A candidate, after failure at any primary examination is required, on admission to any subsequent primary examination, to pay a further fee of £3 3s., which is retained, whether he pass or fail to pass the examination, and which further fee is not allowed as part of the whole fee of £22 for the diploma. The fee of £16 15s. is payable prior to each admission to the Pass Examination; but on each occasion of failure the balance of £11 10s. is returned to the candidate. A candidate having entered his name for either the Primary or Pass Examination, who shall fail to attend the meeting of the Court, for which he shall have received a card, will not be allowed to present himself for examination within the period of three months from the date at which he shall have so failed to attend. A candidate referred on the Primary Examination is required, prior to his admission to re-examination, to produce a certificate of the performance of dissections during not less than three months subsequently to the date of his reference. A candidate referred upon the Primary Examination who shall not obtain more than half of the total minimum number of marks is not readmitted to examination until after the elapse of six months, and is then required to produce, in conformity with the foregoing paragraph, a certificate of the performance of dissections during not less than three months subsequently to the date of his reference. A candidate referred on the Pass Examination is required, prior to his admission to re-examination, to produce a certificate of at least six months' further attendance on the Surgical Practice of a recognised Hospital, together with lectures on Clinical Surgery, subsequently to the date of his reference.

The required certificates, whether for the Primary or Pass Examination, must be forwarded through the post not less than ten clear days prior to the date of each examination; except in the case of a referred candidate whose term of additional study will not expire until the date of the examination, in which case a written application must be sent by him in lieu of the certificates, such certificates to be produced the day before the examination.

A special notice (to be found in our last number, p. 398) has been issued for the information of candidates for the Membership as to the payment of fees for the Primary and Pass Examinations.

ROYAL COLLEGE OF PHYSICIANS, EDINBURGH.

The Licence.—No one can obtain the licence of the College until he has completed the age of twenty-one years.

Every applicant for the licence must produce a certificate that he has studied Vaccination under a recognised teacher.

¹⁶ Candidates can claim exemption from examination in Medicine under the following conditions—viz. 1. The production by the candidate of a degree, diploma, or licence in Medicine entitling him to register under the Medical Act of 1858; or a degree, diploma, or licence in Medicine of a colonial or foreign university approved by the Council of the College. 2. A declaration by the candidate, prior to his admission to the Final Examination for Membership or Fellowship, that it is his intention to obtain either of the medical qualifications mentioned in the foregoing paragraph, in which case the diploma of the College will not be issued to him until he shall produce either the said medical qualification or proof of having passed the several examinations entitling him to receive the same.

¹⁷ This sum of £22 is exclusive of the fee of £2 paid for the Preliminary Examination.

The Preliminary Examination in General Education prescribed by the General Medical Council must have been passed by each applicant, and his name inscribed in the Register of Medical Students, previous to the commencement of his medical studies. Masters and Bachelors of Arts of any British or foreign university, whose course of study may from time to time be approved by the College, will be exempted from the Preliminary Examination; also those who have passed the examination of the national educational bodies, or of any recognised licensing board.

The Professional Examination will be divided into two parts, according to the following arrangement of subjects:—1. Anatomy, Physiology, Chemistry. 2. *Materia Medica* and Pharmacy, Pathology and Pathological Anatomy, Practice of Medicine, Surgery, Midwifery, Medical Jurisprudence, Clinical Medicine. No candidate will be admitted to the first examination until the end of his second winter session, or to the second until he has completed four years of professional study. The examinations will be partly oral, partly in writing.

Candidates for the licence of the College who have passed the First Professional Examination before a qualifying body (provided it be as extensive as that required by this College) will be at once admitted to the second part of the examination.

Meetings for the examination of candidates who already possess a qualification from a recognised licensing body will be held on the first Wednesday of every month (except September and October), and, if necessary, on the following days. Candidates are required to communicate with the secretary of the College not less than eight days before the date of the examination at which they propose to appear.

No candidate is admissible to examination who has been rejected by any licensing board within three months previous to his examination.

The fee payable by a licentiate is £15 15s. In the event of a candidate being unsuccessful at his examination, the sum of £4 4s. will be detained to defray expenses.

Candidates may be admitted to special examination, on other days than those appointed above, on bringing forward reasons satisfactory to the Council, and on paying an extra fee of £5 5s. Should the candidate be unsuccessful, the sum of £11 11s. will be returned to him.

The Membership.—Any licentiate of a College of Physicians, or graduate of a British or Irish University, with whose knowledge of medical and general science the College may be satisfied, may be admitted to the membership provided he shall have attained the age of twenty-four years.

The Fellowship.—No one can be elected a fellow of the College until he has been at least one year a member thereof, and has attained the age of twenty-five years.

The fee to be paid by a member is £31 10s. When a licentiate is raised to the rank of a member, he pays £21. When a member is raised to the rank of a fellow, the fee is £31 10s., exclusive of stamp duty, which amounts to £25. All candidates for fellowship or membership must lodge their fees, and the amount of stamp duty payable at the time to Government, with the treasurer, previously to presenting their petitions.

Qualification in Public Health.—The College now confers certificates of competency in Public Health. Examinations are held in April and October. Fee for certificate, £10 10s.

ROYAL COLLEGE OF SURGEONS, EDINBURGH.

Every candidate for a surgical diploma must have followed his course of study in a university or in an established school of medicine, or in a provincial school specially recognised by the College of Surgeons of that division of the United Kingdom in which it is situate.

Preliminary Examination.—All students who intend becoming candidates for the diploma of the College must have passed the complete examination in general education as prescribed by the General Medical Council, and have had their names inscribed in the Register of Medical Students at the commencement of their professional studies. Examinations will be held on October 16th and 18th, 1880; April 12th and 13th, 1881; July 9th and 11th, 1881. Testimonials of proficiency granted by educational bodies recognised by the Medical Council exempt students from the Preliminary Examination.

Professional Education.—Candidates commencing professional study after Sept. 16th, 1866, must have been engaged during forty-five months after the examination in general education, in professional study, which shall include not less

than four winter sessions', or three winter and two summer sessions' attendance at a recognised medical school.

Professional Examination.—Candidates are subjected to two Professional Examinations, conducted at separate sittings, partly in writing and partly orally.

The First Examination embraces Anatomy, Physiology, and Chemistry. Examinations will be held October 19th, 1880; Jan. 25th, March 29th, April 19th, July 19th, 1881.

Candidates who desire to pass the First Professional Examination must apply to the Secretary on or before the Friday preceding the day of examination, and must produce certificates of attendance in regard to all those courses of study which have reference to the subjects of that examination. They must also produce evidence of having passed the Preliminary Examination. The sum of £6 6s. must be paid to the treasurer of the College for this examination not later than 9 A.M. of the Saturday preceding it. This sum will be considered as paid to account of the entire fee of £15 15s. payable for the diploma.

The Second Examination embraces Surgery and Surgical Anatomy; also Medicine, Midwifery, *Materia Medica*, and Medical Jurisprudence; and does not take place before the termination of the winter session of the last year of study; in the case of candidates who began their course of study after 16th of September, 1866, it will not take place till forty-five months after the examination in general education.

Application for examination must be made to the secretary not later than the Monday previous to the day of the examination.

Every candidate must produce to the secretary—1. Satisfactory evidence of his having attained the age of twenty-one years, and of having been duly registered. 2. The certificates of his classes. 3. The certificate of his having passed the First Professional Examination. And 4. A tabular statement (for which a printed form will be furnished) exhibiting the full amount of his professional education, and distinguishing the classes, hospitals, dispensaries, and schools attended during each session of his studies. If he have been an apprentice, he must also insert the name of his master, the date of his indenture, and the length of time for which he is bound. This statement, accurately filled up, must be attested by his signature, and afterwards delivered by the candidate to the officer of the College, to be preserved by the College. If the candidate have been an apprentice to a Fellow of the College, he must also produce his discharged indenture. The secretary will then give the candidate a letter authorising the examiners to admit him to examination.

The remaining fee payable to the College (being £9 9s.), together with the receipt for the fee paid for the First Professional Examination, must be lodged, not later than 9 A.M. of the Tuesday preceding the examination day, in the hands of the treasurer. £5 5s. will be returned to unsuccessful candidates.

Candidates who have passed the First Examination in Anatomy, Physiology, and Chemistry, at any of the licensing boards recognised by the Medical Act, will be admissible to the Second Professional Examination on producing certificates of the whole course of study, of having passed their Preliminary and First Professional Examinations, and of having been registered. If any of the three subjects of the first examination have been omitted, such candidates will have to undergo the first examination on the omitted subjects; and none of the subjects set down will be omitted at the second examination, even if some of them should have formed part of the first examination by another board. The fee is £15 15s. Unsuccessful candidates under this regulation receive back £11 11s.

In order to test more effectually the practical knowledge of candidates, recent dissections, anatomical specimens, and articles of the *materia medica* will be employed during the examinations; and all candidates will be required to write out formulæ of prescriptions. They will also be subjected to a practical clinical examination in the surgical hospital, including the application of surgical apparatus, &c.

No candidate will be admissible to examination who has been rejected by any other licensing board within the three months preceding his application to be examined.

Those candidates who have passed the First Professional Examination before the 31st December, 1877, will be required to pay, as under the old regulation, a fee of £6 for the second examination, provided they appear for that examination prior to 1st January, 1880; and in the event of being unsuccessful £2 will be retained.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS, EDINBURGH.

The Royal College of Physicians of Edinburgh, and the Royal College of Surgeons of Edinburgh, while they still continue to give their diplomas separately, under separate regulations, have made arrangements by which, after one series of examinations, the student may obtain the diplomas of both Colleges. The general principle of this joint examination is, that it shall be conducted by a board in which each body is represented in those branches which are common to both medicine and surgery; but that the College of Physicians shall take exclusive charge of the examination in Medicine, and the College of Surgeons of the examination in Surgery. The object of the joint examination is to give to students facilities for obtaining from two separate bodies, and at less expense, a qualification in Medicine and a qualification in Surgery. Students passing that examination successfully will be enabled to register two qualifications under the Medical Act—Licentiate of the Royal College of Physicians of Edinburgh, and Licentiate of the Royal College of Surgeons of Edinburgh. The arrangement for thus conferring a double qualification by the co-operation of the two Colleges is in conformity with Section 19 of the Medical Act, and has received the special sanction of the General Council of Medical Education and Registration.

FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

Preliminary Examinations in General Literature, in accordance with the regulations of the General Council, will be held in the Faculty Hall during the session 1880-81 on the following Fridays, commencing at 11 o'clock—namely, October 22nd, 1880, April 15th, July 8th, and September 9th, 1880; and on each occasion the examination will be continued on the succeeding day. Those who are unsuccessful may appear at one subsequent examination without paying a second fee. The fee for the examination and certificate is 10s.

The course of study for the diploma and the regulations generally correspond with those required by the Royal College of Surgeons of Edinburgh.

The Professional Examinations are held at four periods in 1880—in January, April, July, and October. The following are the dates at which the first examination will begin in 1880-81: Oct. 12th, 1880; Jan. 11th, April 5th, July 19th, 1881. The second examination will commence on Oct. 14th, 1880; Jan. 13th, April 8th, and July 21st, 1881. Candidates will not be admitted to the final examination until the expiry of forty-five months from the date of registration, which period must embrace at least three winter and two summer sessions, or four winter sessions, of study at a medical school.

The regulations regarding examinations are nearly similar to those of the Royal College of Surgeons of Edinburgh.

The fee for the diploma is fifteen guineas—six guineas for the first and nine guineas for the second examination. Candidates not already qualified in Medicine are examined in that subject orally and clinically, as well as by written papers.

REGULATIONS REGARDING THE DOUBLE QUALIFICATION.

The Faculty of Physicians and Surgeons of Glasgow and the Royal College of Physicians, Edinburgh, grant their diplomas conjointly before a board of examiners in which each body is represented, the object being to give to students facilities for obtaining from two separate bodies, and at less expense, a double qualification in Medicine and Surgery. Students passing this examination successfully will be enabled to register two qualifications under the Medical Act—namely, Licentiate of the Faculty of Physicians and Surgeons of Glasgow, and Licentiate of the Royal College of Physicians of Edinburgh. The curriculum of study embraces a course of Medicine, in addition to the subjects required for a diploma of the Faculty. The fee for the first examination is eight guineas; for the second twelve guineas.

The examination for the Double Qualification will begin in the Faculty Hall, Glasgow, at the following periods—namely, first examination, October 12th, 1880; January 11th, April 5th, July 19th, 1881. The second examination will begin on October 19th, 1880; January 17th, April 11th, and July 25th, 1881.

Applications to be admitted to either the first or second

examination must be made to the Secretary of the Faculty not later than one week preceding the examination.

Candidates are required to subscribe a declaration that they have not been rejected by any examining board within three months before the examination.

The other regulations are nearly the same as those for the diploma of the Faculty.

KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.

Examinations for the licences of the College in Medicine and Midwifery are held in the week following the first Friday in each month, except August and September. Every candidate for a licence must return his name to the Registrar of the College, and lodge with him his certificates, bank receipt of fees, and his schedule, at least four days before the first Friday in each month. Special examinations will be held at such times as the President may appoint.

Licence in Medicine.—Every candidate for the licence of the College to practise Medicine must produce satisfactory evidence—1. Of character, from a Fellow of the College, or from two registered practitioners. 2. Of having passed an examination in general education, held by some one of the examining bodies recognised by the General Medical Council. 3. Of having been engaged during a period of four years in the study of Medicine. 4. Of having attended courses of lectures on the following subjects, at schools recognised by the College: Practical Anatomy, two courses; Physiology or Institutes of Medicine, Chemistry, Practical Chemistry, Materia Medica, Medical Jurisprudence, Practice of Medicine and Pathology, Surgery, and Midwifery—each one course. 5. Of having attended for twenty-seven months a recognised Medico-Chirurgical Hospital, in which clinical lectures and clinical instruction in Medicine are given, the attendance not to be for more than nine months in any one year—viz., six winter, and three summer months—for not less than three months. 6. Of having studied Fever in a recognised clinical hospital, containing fever wards, and recorded from daily personal observation at least five cases of fever, to the satisfaction of the attending clinical physician, as attested by his signature. 7. Of having attended Practical Midwifery and Diseases of Women for six months at a Lying-in Hospital or Maternity recognised by the College; or, where such hospital attendance cannot have been obtained during the course of study, of having been engaged in Practical Midwifery under the supervision of a registered practitioner holding public appointments; in either case, not less than twenty labour cases must have been actually attended. 8. Of having lodged the admission fee in the Bank of Ireland to the credit of the College.

The professional examination is divided into two parts: 1. Anatomy, Physiology, Chemistry, and Materia Medica. 2. Practice of Medicine, Clinical Medicine, Pathology, Medical Jurisprudence, Midwifery, Hygiene, and Therapeutics. Candidates may be examined in the subjects of the first part at the termination of the second year of study, on producing the certificates in these subjects, or in all the subjects of their education, on the completion of their medical studies. No candidate can be examined in all the subjects of the first and second parts in the same month.

Candidates qualified as follows are required to undergo the second part only of the professional examination, viz.:—(1) Graduates in Medicine of any University in the United Kingdom, or of any Foreign University approved by the College; (2) Fellows, Members, or Licentiates of the Royal College of Physicians of London or Edinburgh; (3) Graduates or Licentiates in Surgery; (4) Candidates who, having completed the curriculum laid down above, shall have passed the previous professional examination or examinations of any of the licensing medical authorities in the United Kingdom. Candidates thus qualified, as specified in Sections 1, 2, and 3, must fill up a schedule and present their registration certificate (or their medical or surgical qualification), as well as certificates of character, of practical midwifery, and of attendance on a clinical hospital which receives cases of fever. Candidates who case is met by Section 4 must produce, in addition to the certificates required from candidates for the licence, a certificate from the licensing medical authority to the effect that such previous professional examination has been successfully passed.

Registered practitioners of five years' standing are admitted to examination for the licence in medicine on producing their certificate of registration with satisfactory

reference, and are exempted from the examination by printed questions.

Candidates who have passed the examinations for the licence in medicine must attend at the College on the Friday following, to subscribe the declaration, and to sign the roll of licentiates in medicine.

Unsuccessful candidates may be admitted to re-examination after not less than two months.

Licence in Midwifery.—Candidates for the licence in midwifery, who are not licentiates in medicine, may be admitted to examination on the following qualifications: (1) The degree or licence in medicine or surgery from any University or College of Physicians or Surgeons in the United Kingdom; (2) Testimonials as to character; (3) Certificates of having attended (a) a course of lectures on midwifery in a school recognised by the College; (b) practical midwifery and diseases of women, as in Section 6 of the regulations for the Licence in Medicine.

Candidates who are licentiates in medicine of the College, or who have passed the examination for such licence, may be admitted to examination for the licence in midwifery on lodging their fees and signifying their wish to the registrar a week at least before such examination.

The fees are: For the licence to practise medicine, £15 15s., which may be divided as follows—viz., examination at the termination of the first period of study, £5 5s.; final examination, £10 10s. Examination for the licence to practise midwifery, £3 3s. Examination for the licences in medicine and midwifery, if obtained within a month, to be lodged in one sum,¹⁸ £16 16s. Special examination for the licence to practise medicine, £21; for the licence to practise midwifery, £5 5s. The admission fee, less the sum paid to the examiners, is returned to any candidate rejected at any of the College examinations.

The Membership.—Members of the College alone are eligible to the Fellowship. Every candidate for the membership is required to produce satisfactory evidence—1. Of having attained the age of twenty-five years. 2. Of being a licentiate of this College for three years at least; or a licentiate of one year's standing, who shall be a graduate of Arts of a university in the United Kingdom at the time of his obtaining the licence; or, a licentiate of one year's standing, who shall be a registered practitioner of seven years' standing at the time of his obtaining the licence. 3. Of professional conduct and moral character, as testified by a fellow or member of the College, or by a fellow of the Royal College of Physicians of London or of Edinburgh. 4. That he is not engaged in trade; and that he does not directly or indirectly vend medicines or drugs; and that he does not dispense or compound medicines for anyone—even his own private patients—(except in cases of extreme urgency); nor practise medicine or surgery in partnership, by deed or otherwise. 5. Of having attended courses of practical instruction in Ophthalmology and Histology. 6. Of having held, during, at least, six months, the office of resident physician, or resident medical pupil, in a hospital recognised by the College; or of having acted for the same period as clinical clerk in the medical wards of such hospital; or of having been in medical charge, for at least twelve months, of any public institution for the treatment of the sick. 7. Of having lodged the admission fee of twenty guineas in the Royal Bank of Ireland to the credit of the College.

Every candidate shall be required to pass an examination in Medical Anatomy, Pathology, Histology, Medical Chemistry, Forensic Medicine, Principles of Public Health, including Climatology and Meteorology, Psychology, and Clinical Medicine. He shall also be required to translate into English a passage from a Latin author, or to show that he possesses a knowledge of Greek, or French, or German.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

Registered pupils who pay a fee of five guineas are admitted to the Preliminary Examination of the College without further fee, and may study each week-day in the Museum from 11 o'clock A.M. to 3 o'clock P.M., and read in the Library from 10 o'clock A.M. to 6 o'clock P.M. They are also permitted to attend the lectures on Comparative Anatomy, and to obtain a certificate for such attendance without payment of any fee. These privileges are open to the students of any school recognised by the Council who may have enrolled themselves as registered pupils of the College.

Students who are not registered pupils (whilst expected to register previous to the commencement of their professional studies) may present themselves for the Preliminary Examination at any period previous to the commencement of professional studies upon payment of £1 1s. as matriculation fee.

The following are the subjects for the Preliminary Examination:—The English language (Grammar and Composition), Arithmetic (Vulgar and Decimal Fractions), Algebra (Simple Equations), Geometry (first two books of Euclid), Greek and Latin (Translation and Grammar); in Greek, the Gospel of St. John, or the first book of Xenophon's Anabasis, or the Dialogue of Lucian entitled "Menippus or the Necromancy"; in Latin the *Æneid* of Virgil, books 1 and 2, or the Jugurthine War of Sallust, or the Third Book of Livy. These examinations are held quarterly—viz., on the third Wednesday in January, April, July, and October in each year. Fee, free to registered pupils; for non-registered pupils, £1 1s. Candidates are required to enter their names, and to pay their fees to the registrar, at least six days previous to the day of examination. N.B.—Students who have passed any of the Preliminary Examination Boards recognised by the General Medical Council, into the curriculum of which the Greek language enters as a compulsory subject, are exempt from further preliminary examination, and are entitled to become registered pupils.

Every registered pupil is admitted, upon payment of a special fee of five guineas, to a special examination for letters testimonial. He must pay a sum of twenty guineas, fifteen guineas of which will be returned if rejected.

Stated examinations are held in April, July, and November, commencing on dates of which due notice will be given beforehand by the Council of the College, and to which candidates cannot be admitted unless they be registered pupils, and at which they will be divided into two classes—junior and senior. The junior class will be examined in Anatomy, Histology, Physiology, Materia Medica, and Chemistry. The fee for this examination is five guineas, in addition to the registration fee of five guineas; but to be allowed the candidate in case he presents himself a second time for examination. The senior class must produce certificates of having attended three courses of lectures on the Theory and Practice of Surgery, one course of lectures on the Practice of Medicine, and one course of lectures on Midwifery; also certificates of attendance on a recognised hospital for three winter and three summer sessions. This class will be examined in Surgery, Operative Surgery and Surgical Appliances, Practice of Medicine, Medical Jurisprudence and Prescriptions. No candidate for letters testimonial will be admitted to examination without producing a certificate of attendance for one month at the Cow-Pock Institution, or some other institution to be approved of by this Council, under the instruction of a public vaccinator specially recognised by this College for the purpose, and that he is practically acquainted with vaccination. The fee for this examination is fifteen guineas; returnable to the candidate in case of rejection. In addition to the foregoing fees a fee of one guinea is to be paid to the registrar.

The Fellowship.—Every registered pupil or licentiate may be admitted to examination for the Fellowship if he shall have lodged in the Bank of Ireland, for the use of the College if he be a licentiate, the sum of twenty guineas, or thirty-five in case he be only a registered pupil; provided in either case he intends to reside beyond ten miles from Dublin, or, if he reside in Dublin, or within ten miles thereof, he must lodge thirty guineas, or if he be only a registered pupil, forty-five guineas. He must be twenty-five years of age, and be a Bachelor of Arts of some university, or show that he has obtained a liberal preliminary education. He must, moreover, produce a certificate of general good conduct and certificates of attendance on the several courses of lectures required to be attended by candidates for letters testimonial, together with one course of lectures on Comparative Anatomy, and one course of lectures on Natural Philosophy. A thesis on some medical subject, or clinical reports, with observations, of six or more medical or surgical cases taken by himself will also be required, and certificates of having been engaged in the acquisition of professional knowledge for a period of not less than six years, three of which must have been spent in one or more of the schools and hospitals recognised by the Council. Licentiates of the College who may not be able to show that they have followed the course of study specified in the preceding regulations, may, at the expiration of ten years from the date of their diploma, be

¹⁸ Any candidate rejected at the Examination for the Licence in Medicine must pay the full fee of £3 3s. for the Licence in Midwifery.

admitted to the examination required for the Fellowship, provided they produce such evidence as shall be satisfactory to the Council that they have conducted themselves honourably in the practice of their profession.

Examination of Candidates for Letters Testimonial, special and stated, will be held in April, July, and November, upon such days as the Council may direct.

Junior classes will be examined in Dissections, Anatomy, Physiology, Histology, Materia Medica, and Chemistry, written and *visû voce*. The senior class will be examined in Surgery, Practice of Medicine, Medical Jurisprudence, and Prescriptions, written and *visû voce*, and in Clinical Examination and Operative Surgery.

The fees to be paid by candidates for letters testimonial are:—Registration fee, £5 5s.; Junior Class Examination fee, £5 5s.; Senior Class Examination fee, £15 15s.; total, £26 5s. In addition to the foregoing, a fee of £1 1s. is to be paid to the registrar on handing each licentiate his diploma.

Examinations for the Fellowship will be held from time to time as the Council may direct. The subjects of the First Examination will be Anatomy and Physiology (human and comparative); those of the second, Pathology, Therapeutics, the Theory and Practice of Medicine and Surgery, and Clinical Surgery. In cases of licentiates of ten years' standing, the examinations will be mainly clinical and practical. In addition to the oral examinations, candidates will be required to give written answers to either written or printed questions, and to perform Dissections and Operations.

THE SOCIETY OF APOTHECARIES, LONDON.

Every candidate for a Certificate of Qualification to practise as an Apothecary will be required to produce testimonials—Of having passed a Preliminary Examination in Arts as a test of general education. (This examination must be passed before the commencement of medical studies. Medical studies commenced before the candidates shall have passed an examination on the subject of general education will not be recognised.) Of having attained the full age of twenty-one years. Of good moral conduct. A certificate of three months' Practical Pharmacy from some recognised hospital or dispensary, or from a qualified medical practitioner. And of having pursued a course of medical study in conformity with the regulations of the Court.

The course of medical study required for a licence must occupy at least four years, of which not less than three winter and two summer sessions must be passed at a recognised school or hospital. The following will be recognised and considered equivalent to eighteen months' study, in addition to the two years and a half above mentioned: (a) attendance on the practice of a hospital or other public institution recognised by this Hall for that purpose; (b) instruction as the pupil or assistant of a registered practitioner, physician or surgeon to a hospital, general dispensary, or union workhouse, or where such opportunities of practical instruction are afforded as may be deemed satisfactory.

Course of Study.—Every candidate must attend the following lectures and medical practice: each winter session to consist of not less than six months, to commence on the 1st and not later than the 15th of October; each summer session to commence on the 1st and not later than the 15th of May.

First Year.—Winter Session: Chemistry, Anatomy, and Physiology (including Dissections and Demonstrations). Summer Session: Botany, Materia Medica and Therapeutics, Practical Chemistry.

Second Year.—Winter Session: Anatomy and Physiology (including Dissections and Demonstrations), Principles and Practices of Medicine, Clinical Medical Practice. Summer Session: Midwifery and Diseases of Women and Children. Forensic Medicine and Toxicology, Clinical Medical Practice.

Third Year.—Winter Session: Principles and Practice of Medicine, Clinical Medical Lectures, Morbid Anatomy, Pathology and Clinical Medical Practice. Summer Session: Practical Midwifery and Vaccination, Morbid Anatomy, Clinical Medical Practice.

No certificates of lectures or of anatomical instructions delivered in private to particular students apart from the ordinary classes of recognised public medical schools, can be received by the Court of Examiners.

Examination in Arts.—This examination will be held at

the Hall of the Society on Friday and Saturday, January 23rd and 24th, April 23rd and 24th, September 17th and 18th. The examination will be conducted by means of printed papers. Candidates will be examined in the following branches; and no candidate will be approved unless he show a competent knowledge of each branch of the examination:—1, the English Language; 2, the Latin Language; 3, Mathematics; 4, one of the following subjects, at the option of the candidate—Greek, French, German, Natural Philosophy. Testimonials of proficiency in general education will be received from any of the licensing bodies, and also from recognised national, colonial, and foreign educational bodies—viz., a degree in Arts of any university of the United Kingdom, or of the colonies, or of such other universities as may be specially recognised from time to time by the Medical Council.¹⁹ The fee for the examination is one guinea. If a candidate fail to pass the examination, the fee will not be returned to him, but he will be admissible to either, or to both, of the two next following examinations without payment of an additional fee, upon giving at least one week's notice.

Prizes are annually offered for proficiency in the knowledge of Materia Medica and Pharmaceutical Chemistry.

Professional Examinations.—The Court of Examiners meet in the Hall every Wednesday and Thursday, where candidates are required to attend at 4.30 P.M. Every candidate intending to offer himself for examination must give seven days' notice previous to the day of examination, and must at the same time deposit all the required certificates with the fee, at the office of the beadle, where attendance is given daily from 10 till 4 o'clock; Saturdays, 10 till 2. Certificates in arts granted by any of the bodies whose certificate is recognised by the Medical Council, will be accepted from candidates who present themselves at the Professional Examination at the Hall, as equivalent to their having passed the above examination.

The examination of candidates is divided into two parts, and is conducted partly in writing and partly *visû voce*.

The First Examination, which may be passed after the second winter session, embraces the following subjects:—Physicians' Prescriptions and Pharmacy; Anatomy and Physiology; General and Practical Chemistry; Materia Medica and Botany; Histology. Testimonials are required of candidates for the First Examination of having passed an examination in arts recognised by the Medical Council; of having completed the curriculum of study to the close of the second winter session; of having attended three months' Practical Pharmacy; and of good moral conduct. (Any candidate who presents himself for the First Examination and is rejected, may be admitted to re-examination at the expiration of three calendar months.)

The Second Examination, at the termination of the medical studies, embraces Principles and Practice of Medicine; Pathology and Therapeutics; Midwifery, including the diseases of Women and Children; Forensic Medicine and Toxicology; Microscopical Pathology.

Certificates are required of candidates for the Second or Pass Examination, of having completed four years' medical study, including the period spent at the hospital; of being twenty-one years of age; and of good moral conduct. Of having passed the First Examination. Of having completed the prescribed curriculum of study according to the schedule, including a personal attendance of twenty cases of midwifery; and of having received instruction in Practical Vaccination, and vaccinated not less than twenty cases. Of having served the office of clinical clerk at a recognised hospital during the period of six weeks, at least. Of having been examined at the class examinations instituted by the various lecturers and professors of their respective medical schools and colleges.

¹⁹ The following is a syllabus of subjects for examination in 1881.—1. *The English Language*: The leading features of its history, its structure and grammar. English Composition. 2. *The Latin Language*: Livy, book i. caps. 1. to xli. Horace, Odes, book iv. Re-translation of easy sentences. Grammatical questions will be introduced into the Latin paper, and each candidate will be expected to give satisfactory answers to these. 3. *Mathematics*: The ordinary rules of Arithmetic. Vulgar and Decimal Fractions. Addition, Subtraction, Multiplication, and Division of Algebraical Quantities. Simple Equations. The first two books of Euclid. 4. (a) *Greek*: Homer, Iliad, book i. Grammatical questions. (b) *French*: Voltaire, Histoire de Charles XII. Grammatical questions. (c) *German*: Lessing, Mina von Barnhelm. Translation from English into German. Grammatical questions. (d) *Natural Philosophy*: Mechanics. Hydrostatics and Pneumatics. (The books recommended for study in this subject are Smith's "Statics," and Smith's "Hydrostatics," or Newth's "Natural Philosophy.")

Modified Examination.—Graduates in Medicine of British Universities will be admitted to a Clinical and Practical Examination in the Practice of Medicine, Pathology, and Midwifery.

No rejected candidate for the licence can be re-examined until the expiration of six calendar months.

Fees.—For a Certificate of Qualification to Practise, six guineas, half of which is retained in case of rejection, to be accounted for at a subsequent examination. For the First Examination, three guineas, which sum is retained in case of rejection and accounted for subsequently. For the Second Examination, three guineas. For an Assistant's Certificate two guineas, which sum is retained in case of rejection and accounted for subsequently. N.B.—After two rejections a second fee of three guineas will be required, or one guinea in the case of an Assistant.

APOTHECARIES' HALL OF IRELAND.

The *Arts Examination* will be held at the Hall four times in the year—viz., the third Thursday in January, April, July, and October, at 12 o'clock.

Professional Education.—Every candidate for the licence to practise Medicine and Pharmacy must produce certificates to the following effect:—Of having passed an examination in Arts previously to entering on professional study. Of registration as a medical student from the Registrar of the Medical Council.²⁰ Of being at least twenty-one years of age, and of good moral character. Of pupillage to a qualified apothecary, or of having been otherwise engaged at *practical* Pharmacy for a period of twelve months subsequent to having passed the examination in Arts. Of having spent four years in professional study. Of having attended the following courses—namely: Chemistry, during one winter session; Anatomy and Physiology, during one winter session; Demonstrations and Dissections, during two winter sessions; Botany and Natural History, during one summer session; Practical Chemistry (by daily instruction in a recognised laboratory), during three months; *Materia Medica*, during three months; Principles and Practice of Medicine, during one winter session; Midwifery and Diseases of Women and Children, during six months; Practical Midwifery at a recognised hospital (attendance upon twenty cases); Surgery, during one winter session; Forensic Medicine, during one summer session; instruction in the practice of Vaccination. Of having attended at a recognised hospital or hospitals the Practice of Medicine and Clinical Lectures on Medicine, during two winter and two summer sessions; also the Practice of Surgery and Clinical Lectures on Surgery, during one winter and one summer session. Of practical study, with care of patients, as apprentice, pupil, assistant, clinical clerk, or dresser, in hospital, dispensary, or with a registered practitioner, who can supply the necessary means of instruction. Of having performed Vaccination successfully under a vaccinator recognised by the Local Government Board.

The *Examination for the Licence* is divided into two parts. The first part comprehends Chemistry, including Physics, Botany, Anatomy, Physiology, *Materia Medica*, and Pharmacy; the second, Medicine, Surgery, Pathology, Therapeutics, Midwifery, Forensic Medicine, and Hygiene.

Candidates at the examination on Anatomy are liable to be called on to perform dissections; and at the examination on Surgery, to perform operations on the dead subject.

The *Professional Examinations* will be held quarterly, and will commence on the first and second Monday in January, April, July, and October. They will be carried on as follows:—The first part, on the first Monday, at eleven o'clock A.M.; and on the Tuesday and Wednesday succeeding, at the same hour. Subjects: Chemistry, including Chemical Physics, and Botany, Monday; Anatomy and Physiology, Tuesday; *Materia Medica* and Pharmacy, Wednesday. The second part, or final examination, on the second Monday, at eleven o'clock A.M.; and on the Tuesday and Wednesday succeeding, at the same hour; on Thursday Clinical Examination. Subjects: Medicine and Surgery, including Pathology and Therapeutics, Monday; Midwifery and Diseases of Women and Children, Tuesday; Forensic Medicine and Hygiene, Wednesday; Clinical Examination, Thursday.

²⁰ A person, having first passed an examination in Arts, may be registered as a "medical student" who has commenced the study of the profession either at a medical school, hospital, or as an apprentice or pupil to a registered practitioner.

ARMY MEDICAL DEPARTMENT.

6, Whitehall-yard, S.W.

Appointments in the Army Medical Department are obtained by competitive examination, held in London twice a year—in February and August. A candidate must be twenty-one years of age, and not over twenty-eight, in good health, and physically fit for service, and both his parents of unmixed European blood. He must possess diplomas or licences to practise Medicine and Surgery recognised by the General Medical Council, and must be registered under the Medical Act; and he must furnish satisfactory certificates that he is of regular and steady habits, and likely in every respect to prove creditable to the department. The subjects of examination, and the marks which may be gained for each, are as follows:—*Compulsory subjects*: Anatomy and Physiology, 1000; Surgery, partly Practical, 1000; Medicine, including Therapeutics, the Diseases of Women and Children, 1000; Chemistry and Pharmacy, and a practical knowledge of Drugs, 1000. *Voluntary subjects*: French and German (150 each), 300; Natural Sciences, 300.

After passing the competitive examination, the candidates are sent to Netley, where they are required to attend a four months' course of practical instruction in Hygiene, Clinical and Military Medicine, Clinical and Military Surgery, Pathology of Diseases and Injuries incident to Military Service. During this course they will be provided with quarters, receive 8s. a day pay, and have the relative rank of lieutenant in the army. The Secretary of State for War has power to nominate, without a competitive examination, on the recommendation of the governing bodies of public schools of medicine in the United Kingdom or the colonies, a number of probationers, not exceeding half the vacancies in the Department, but this power has never yet been exercised.

The following table of the rates of pay, half-pay, and gratuity may probably prove interesting to students who think of entering the service:—

Rank.	Rates of Pay.	Half-pay & Gratuities.	Relative Military Rank.
	Daily.		
Surgeon on probation ..	£0 8 0 ..	—	Lieutenant
	Annual.		
Surgeon ..	200 0 0 ..	—	Captain
" aft. 5 years' service	250 0 0 ..	—	
	Daily.	Gratuity.	
Surgeon-Major ..	0 15 0 ..	£1250 ..	
" aft. 15 years' service	1 0 0 ..	—	Major
" aft. 18 ..	1 2 6 ..	£1800 ..	
" ..	—	£2500 ..	
	Half-pay.		
" 20 ..	1 5 0 ..	£1 0 0 ..	Lieut.-Col.
" 25 ..	1 7 6 ..	1 2 6 ..	
" 30 ..	—	1 5 0 ..	
Brigade-Surgeon ..	1 10 0 ..	—	
" aft. 5 years in rank	1 13 0 ..	—	
" aft. 20 years' service	—	1 7 6 ..	
" 30 ..	—	1 10 0 ..	
Deputy Surgeon-General ..	2 0 0 ..	1 15 0 ..	Colonel
Surgeon-General ..	2 15 0 ..	2 0 0 ..	Maj.-General

Surgeons are promoted to be Surgeons-Major on completing twelve years' full-pay service, of which three must have been abroad. Surgeons-Major are promoted to Brigade Surgeons by selection for ability and merit, but must have had eight years' foreign service; and Brigade Surgeons, to be eligible for selection as Deputy Surgeons-General, must have served abroad at least ten years, of which three must have been in India. All officers under the rank of Deputy Surgeon-General are placed on the retired list at the age of fifty-five, and those of that rank and Surgeons-General at the age of sixty.

Medical officers, on the recommendation of a Board, are allowed six months' sick leave on full pay; and this may be extended for a further period of six months on the recommendation of the Director-General. Medical officers on full pay are entitled to quarters and a soldier servant, or a money allowance in lieu thereof; and those having the relative rank of field officer, to forage allowance for one or more horses according to rank.

All applications for information respecting the examinations, and for schedules to be filled up by intending candidates, should be made to the Director-General, Army Medical Department, 6, Whitehall-yard, S.W.

ARMY MEDICAL SCHOOL.

Royal Victoria Hospital, Netley.

All gentlemen who have been successful in the competitive examinations, held twice a year (February and August), in London, for appointments in the medical services of the

Army (British and Indian) and of the Navy, attend subsequently, at the Royal Victoria Hospital, a course of practical instruction in the duties they will have to perform in the public services. The course lasts four months; at the end of the session an examination is held to ascertain the progress made by the candidates, who are afterwards gazetted as surgeons. The Indian and Naval candidates take their seniority according to the aggregate number of marks then gained at both the London and the Netley examinations. The recent Army Medical Warrant has ordained that there shall be no longer any competitive examination at the end of the Netley Course, as heretofore, for the "probationers" of that department; but merely a qualifying or pass examination, empowering the professors of the School to say of each "probationer" that he is either "fit" or "unfit." If "fit" he goes out of Netley with the same marks as he gained at the London examination. He gains no marks from his work at Netley, as heretofore, and as the candidates for the other services do. Competition for the Herbert prize, the Martin Memorial medal, and the Parkes Memorial medal, continues open to the probationers of the Army Medical Department and to the candidates for the Indian and Naval Medical Services. The lectures on Military Surgery include gunshot and other wounds; arrangements for the transport of wounded; duties of army surgeons in the field, during sieges, on transports, &c.; and other special subjects. Those on Military Medicine refer to the tropical and other diseases of the British possessions and colonies, and to the losses by disease in peace and war, at home and abroad. The lectures on Hygiene comprise the examination of water and air, of food, clothing, &c., of the soldier, his duties and exercise, and the circumstances affecting his health; the subjects of meteorology, statistics, and the prevention of the different diseases met with in the army, on home or foreign service. The lectures on Pathology have reference chiefly to Morbid Anatomy and the scientific examination of tropical diseases, and of other complaints which the army surgeon is especially called on to investigate. The candidates also attend the wards of the hospital to study the diseases of invalids under the Professors of Medicine and Surgery, the system of recruiting, and the modes of keeping the army medical returns and records. They are also called on to make post-mortem examinations, to operate on the dead body, and pass through courses of practical instruction in the laboratory on the modes of analysing water and air and of recognising the qualities and adulterations of food, and in the microscope-room on the modes of microscopic examination of morbid tissues and of adulterations of food, &c. Visits are also paid at stated intervals to the lunatic hospital attached to the Royal Victoria Hospital, and instruction is given on the subject of insanity by the surgeon-major in charge.

Candidates for commissions in each branch of the public service, while at Netley, wear uniform, take their meals the Army Medical Department mess, and receive from the Government an allowance towards cost of maintenance.

INDIAN MEDICAL SERVICE.

India Office, St. James's-park, S.W.

All natural-born subjects of Her Majesty, between twenty-two and twenty-eight years of age at the date of examination, and of sound bodily health, may be candidates. They may be married or unmarried. They must possess a diploma in Surgery, or a licence to practise it, as well as a degree in Medicine, or a licence to practise it, in Great Britain or Ireland. They must subscribe and send in to the Military Secretary, India Office, so as to reach that address at least a fortnight before the date fixed for the examination, a declaration containing an attestation that they are ready to proceed on duty immediately on being gazetted, that they labour under no mental or physical disability, and that they possess a recognised degree or licence to practise both Medicine and Surgery. This declaration must be accompanied by proof of age, either by extract from a register of births, or, when such is unattainable, by the candidate's own declaration, form of which can be obtained at the India Office, a certificate of moral character from a magistrate or a minister of the religious denomination to which the candidate belongs, who has personally known him for at least the two years preceding the date of his application; and a certificate of registration, in accordance with the Medical Act of 1858, of the degrees, diplomas and licences possessed by the candidate. The physical fitness of candidates will

be determined by a Medical Board previous to the competitive examination. On producing the foregoing qualifications, the candidate will be examined in the following compulsory subjects:—Anatomy and Physiology, Surgery, Medicine (including Therapeutics and Diseases of Women and Children), Chemistry and Pharmacy, and a practical knowledge of Drugs. The eligibility of each candidate for the Indian Medical Service will be determined by the result of the examinations in these subjects only. Candidates, who desire it, will be examined in French, German, and Hindustani, Comparative Anatomy, Zoology, Natural Philosophy, Physical Geography, and Botany with special reference to *Materia Medica*.

After passing the Preliminary Examination, candidates will be required to attend one entire course of Practical Instruction at the Army Medical School, before being admitted to examination for a commission, on Hygiene, Clinical and Military Medicine, Clinical and Military Surgery, Pathology of Diseases and Injuries incident to Military Service. These courses are to be of not less than four months' duration; but candidates who have already gone through a course at Netley as candidates for the Army or Navy Medical Service may, if thought desirable, be exempted from attending the school a second time. At the conclusion of the course, candidates will be required to pass an examination on the subjects taught in the School. The examination will be conducted by the professors of the School. The position of the candidates on the list of surgeons will be determined by the combined results of the preliminary and of the final examinations, and, so far as the requirements of the service will permit, they will have the choice of Presidency in India, according to their position in that list.

Pay at the rate of 10s. a day will be allowed from date of passing final examination at the Army medical School, until date of embarkation, when a passage is provided, or for a period of two months, when the surgeon is permitted to make his own arrangements for passage. An advance of two months' pay will also be made on embarkation.

N.B.—The examinations for admission to the Indian Medical Service usually take place in February and August.

NAVAL MEDICAL SERVICE.

Admiralty, 9, New-street, Spring-gardens, S.W.

Every candidate desirous of presenting himself for admission to the Naval Medical Service must not be under twenty-one nor over twenty-eight years of age. He must produce a certificate from the district registrar, in which the date of birth is stated; or, if this cannot be obtained, an affidavit from one of the parents or other near relative, who can attest the date of birth will be accepted. He must also produce a certificate of moral character signed by a clergyman or a magistrate, to whom he has been for some years personally known, or by the president or senior professor of the college at which he was educated. The candidate must make a declaration that he labours under no mental or constitutional disease, nor any imperfection or disability that can interfere with the most efficient discharge of the duties of a medical officer in any climate. He must also attest his readiness to engage for general service, and to proceed on foreign service when required to do so. The candidate must be registered under the Medical Act in force at the time of his appointment as licensed to practise medicine and Surgery in Great Britain or Ireland.

Candidates will be examined by the Examining Board in the following subjects:—Anatomy and Physiology; Surgery; Medicine (including Therapeutics and the Diseases of Women and Children); Chemistry and Pharmacy, and a practical knowledge of drugs. (The examination in Medicine and Surgery will be in part practical, and will include operations on the dead body, the application of surgical apparatus, and the examination of medical and surgical patients at the bedside.) Eligibility will be determined by the result of the examinations in these subjects only.

Candidates who desire it will be examined in Comparative Anatomy, Zoology, Natural Philosophy, Physical Geology, and Botany with special reference to *Materia Medica*, also in French and German; and the number of marks gained in these subjects will be added to the total number obtained in the obligatory part of the examination by candidates who shall have been found qualified for admission, and whose position on the list of successful competitors will thus be improved in proportion to the knowledge of these branches of science.

METROPOLITAN HOSPITALS AND MEDICAL SCHOOLS.

ST. BARTHOLOMEW'S HOSPITAL AND COLLEGE.—The clinical practice of the hospital comprises a services of 710 beds, of which 676 are in the hospital at Smithfield, and 34 are for convalescent patients at Lauderdale House, Highgate.

Four house-physicians, four house-surgeons, and a mid-wifery assistant are appointed annually, each of them holding office for one year, and provided with rooms by the hospital authorities. The ophthalmic house-surgeon is appointed for six months, and is eligible for re-election for a second term of six months. The assistant chloroformist is appointed annually, and is provided with rooms. No fee is paid for any of these appointments, and each receives a salary of £25. The clinical clerks, the obstetric clerks, the clerks to the medical out-patients, the dressers to the surgical out-patients, and the dressers in the special departments are chosen from the diligent students. Thirty-two ward-dresserships are given annually to the students who pass the best examination in the subjects of study of the first year. Other ward-dresserships may be obtained by payment of the usual fees.

A college is attached to the hospital, in which students can reside, subject to the college regulations.

Foundation and other Prizes.—Open Scholarships in Science of the value of £130 each, tenable for one year, will be competed for September 25th. Candidates must not be more than twenty-five years of age for one, and twenty-one for the other, and must not have entered to the medical or surgical practice of any metropolitan medical school. The subjects of examination are Physics, Chemistry, Botany, and Zoology.—Preliminary Scientific Exhibition (founded 1873). The subjects of examination are identical with those of the Open Scholarship in Science. This Exhibition, of the value of £50, is tenable for one year. The examination is confined to students of the hospital of less than six months' standing, and will be held October 28th. The Jeaffreson Exhibition, of the value of £50, and tenable for two years, is awarded after examination, beginning September 25th, in the subjects of General Education. It is now an Open Exhibition. A Senior Scholarship, £50, in Anatomy, Physiology, and Chemistry. Lawrence Scholarship, and Gold Medal, of the value of forty guineas (founded in 1873 by the family of the late Sir Wm. Lawrence). Two Brackenbury Scholarships in Medicine and Surgery, £30 each. Junior Scholarships in the subjects of study of the first year: 1st, £50; 2nd, £30; 3rd, £20.

CHARING-CROSS HOSPITAL AND COLLEGE.—The fee for matriculation, which involves no examination, is £2 2s., to be paid on entering. Matriculated students pay proportionately lower fees, and are admitted without additional fee to the special courses in Practical Surgery, the lectures on Psychological Medicine, to the Physiological Laboratory for practical instruction in Histology, and to the practice of the Royal Westminster Ophthalmic Hospital. They alone are entitled to compete for the scholarships, medals, and prizes.

Two Entrance Scholarships, of the value of £30 and £20 respectively, tenable for one year, will be awarded annually in October, after a competitive examination in the following subjects:—*Compulsory*, English, Latin, French or German, Mathematics; *Optional* (only one of which may be selected), Chemistry, Mechanics, German or French, the subjects being those of the matriculation examination of the University of London. Candidates must give notice of their intention to compete on or before Wednesday, Sept. 22nd, 1880. Two scholarships are open for competition among the matriculated students: the Llewellyn Scholarship of £25, for students who have just completed their second year; and the Golding Scholarship of £15, for students who have just completed their first year. The Pereira Prize of £5 is open to all matriculated students, and is awarded annually for the best clinical reports.

The various resident appointments are open to all matriculated students without additional fee.

ST. GEORGE'S HOSPITAL.—Perpetual pupils, by payment of £130 in three instalments, or £125 in one sum, are entitled to admission to the medical and surgical practice; to compete for prizes and exhibitions; to hold the appointments of house-physician and house-surgeon, assistant house-

physician, assistant house-surgeon, ophthalmic assistant, and to become clinical clerks for two periods of three months each, and dressers for similar periods. The house-physician and house-surgeon receive their board and lodging free, and no payment is made for the appointment. Gentlemen are admitted to the hospital practice and lectures required by the Colleges of Physicians and Surgeons and the Society of Apothecaries on payment of £45 at the commencement of the first year of study, £45 at the commencement of the second year of study, £20 for the third, and £20 for the fourth year. These payments entitle the pupil to hold the offices of clinical clerk and dresser for three months each, and to become a candidate for the offices of medical and surgical registrar and demonstrator of anatomy and curator of the museum. These are all salaried offices. The obstetric assistant is resident, with a salary of £100.

Prizes.—The William Brown Exhibition of £100 per annum, tenable for two years, open to any perpetual pupil of St. George's who is under twenty-five years of age, and who shall have obtained a diploma or licence entitling him to be registered as a practitioner of medicine or surgery in England, within two years previous to the period fixed for the examination (July). The examination is to test the proficiency of the candidate in Medicine, Midwifery, and Surgery, including Ophthalmic Surgery. The William Brown Exhibition of £40 per annum, tenable for three years, for general fitness for the exercise of the medical profession, and for moral conduct, open to perpetual pupils in their fourth year of study. Sir Charles Clarke's Prize (interest of £200 Consols) for good conduct. The Brackenbury Prize in Medicine, value nearly £40; the Brackenbury Prize in Surgery, value nearly £40; open to all pupils of the hospital.

GUY'S HOSPITAL.—House-physicians and house-surgeons, obstetric residents, dressers, clinical and other clerks, are selected from the students, according to merit, and without payment. The house-physicians, of whom there are three constantly on duty, one as junior and two as seniors, hold office for six months each, the first two months in the former capacity, the other four in the latter. The duty of the junior house-physician is to attend in the medical out-patient room three times a week, in a room adjoining that occupied by the assistant-physician for the day, and prescribe for those patients who are not seen by the assistant-physician. The senior house-physicians are chiefly occupied in the medical wards, and attend to all emergencies that may arise in the absence of the physicians. They have separate rooms in the clinical building, and are boarded at the charge of the hospital. The house-surgeons, of whom there are also three on duty, hold office for six months each. During the first two months the house-surgeon assists in the out-patient department. During the next two months he has the general superintendence of the surgical casualty department, and assists the senior when required; and subsequently, as senior house-surgeon, he lives in the hospital, being boarded free of expense, and in the absence of the surgeons and assistant-surgeons has the care of the patients in the surgical wards. The dressers are selected from those gentlemen who have completed their third winter session, and who have been most diligent in the junior appointments. They hold office for six months each. Three are attached to each surgeon. During their week of special duty they reside in the hospital, and board with the house-surgeons free of expense. Two obstetric residents reside and are boarded in the hospital.

Scholarships, Prizes, &c.—Open Scholarship of the value of £131 5s. in Arts, Latin, Greek, Mathematics, and modern languages. Open Scholarship of £131 5s. in Science. Subjects: Inorganic Chemistry, Zoology, Botany, Physics (these will be competed for on Friday, September 24th). At the end of the summer session: first prize, £50; second prize, £25; third prize, £10 10s. Subjects: Anatomy, Physiology, Chemistry, Materia Medica, and Botany or Comparative Anatomy.—For Students in their second year: First prize, £25; second prize, £10. Subjects: Anatomy, Physiology. The Sands Cox Scholarship of £15 per annum for three years. Subject: Physiology. The Michael Harris Prize, of £10 for Anatomy.—For students in their third year: First prize, £35; second prize, £20. Subjects: Medicine, Surgery, Midwifery, and Medical Jurisprudence.—For Senior Students: The Treasurer's Gold Medal in Medicine; the Treasurer's Gold Medal in Surgery; the Gurney Hoare Prize of £25, for Clinical Medicine and Surgery. The Beane Scholarship, of thirty guineas, for Pathology. The

Physical Society awards the following prizes: Two of £5 each to the members who send in the best essays on selected subjects; prizes of £10 and £5 for the best papers read before the Society; and one of £5 to the member who has most distinguished himself in the debates of the sessions.

The Library is supplied with weekly, monthly, and quarterly journals of medicine, natural history, and philosophy. It is open to the students from 9.30 A.M. to 5.30 P.M.

KING'S COLLEGE.—The physicians' assistants, the physician-accoucheur's assistant, the clinical clerks, and the house-surgeon and dressers, are selected by examination from among those matriculated students of the college who are pupils of the hospital. The College and Hospital fees amount to £125 if paid in one sum on entrance, to £130 if paid in two instalments—viz., £70 on entrance and £60 at the beginning of the second winter session; or to £135 if paid in three instalments—viz., £60 on entrance, £50 at the beginning of the second winter session, and £25 at the beginning of the third. Students are recommended to add to the above the fee for attendance on the Medical Tutors' class for one year—namely, £3 3s. for the first year's subjects, or in the case of those preparing for the Preliminary Scientific Examination of the University of London, £5 5s. All resident students are required to attend the tutor during their first year. Rooms are provided within the walls of the college for the residence of a limited number of matriculated students. Registration fee at hospital 10s. 6d. Rooms and commons are provided at the hospital for the resident officers free of charge.

Scholarships.—Warneford Scholarships: Two of £25 per annum for three years, and one of £25 for two years. Science: One of £50 and one of £25 each for two years. Sambrooke: One of £60 and one of £40 for Science and Literature. College Scholarships: One of £40 per annum, for two years; one of £30, for one year; three of £20 for one year. The Daniell Scholarship of the annual value of £20. Sambrooke Registrarships, of the annual value of £50 each, and tenable for two years, are open to all matriculated students who have filled any one of the higher appointments of the hospital, or who have become Associates. The Leathes Prizes, value £7, and the Warneford Prizes, value £40, are given annually amongst the matriculated medical students. Two medical Clinical Prizes, one of £3 for the winter session, and one of £2 for the summer session, and two Surgical Clinical Prizes, of £3 each, are given. The Todd Medical Clinical Prize consists of a bronze medal and books to the value of £4 4s. The Tanner Prize for Obstetric Medicine, value £10, is given annually in July. All students, occasional as well as matriculated, are admitted to contend for the class prizes.

LONDON HOSPITAL AND COLLEGE.—The Medical School of the London Hospital is under the direction of a College Board, composed of six members of the Hospital Staff, and six of the House Committee. The executive authority is committed to a Warden.

For instruction in Mental Diseases, students can attend, without further fee, the practice of Dr. John Millar, medical superintendent of Bethnal House Asylum, a few minutes' walk from the hospital.

Prizes.—Nine Scholarships to be offered for competition in the winter and summer sessions:—Two Entrance Science Scholarships, awarded at the end of September, of the value of £60 and £40 respectively. Two Scholarships of £30 and £20, to the students who pass in September the best and second-best examinations in the subjects required at the Preliminary Examinations. A Scholarship, value £20, in Human Anatomy, for first-year's students, to be awarded in April, 1879. A Scholarship, value £25, in Anatomy, in Physiology, and Chemistry, for first or second-year's students, to be awarded at the end of the session. Three Hospital Scholarships, value £20 each, for Clinical Medicine and Clinical Surgery, and Clinical Obstetrics. The Duckworth Nelson Prize, value £10, for Practical Medicine and Surgery (biennial). Money prizes to the value of £60 given annually by the House Committee for zeal in dressing outpatients and knowledge of Minor Surgery.

Appointments.—The resident appointments consist of five house-physicians, four house-surgeons, and one accoucheurship. Two dressers and two maternity pupils also reside in the hospital. (N.B. The holders of all the resident offices are provided with rooms and board free of expense.)

There are also three clinical assistants in the out-patient departments, at a salary of £80 each. Medical registrar, salary £100. Surgical registrar, salary £100. There are also numerous appointments for clinical clerks, dressers, maternity pupils, post-mortem clerks, &c.

General fee to lectures and hospital practice, 90 guineas, in one sum, or 100 guineas payable in three instalments of 45, 40, and 15 guineas at the commencement of the first, second, and third years respectively. Special entries can be made to lectures or practice.

ST. MARY'S HOSPITAL.—There are four resident medical officers, three of whom are appointed for twelve months, and one, the obstetric officer, for six months, who board free of expense in the hospital. These appointments are awarded after competition, without additional fee. There is also a resident dressership. A resident registrar is appointed from amongst the students, with a salary of £100 a year and dispensary fees, who resides free of expense in the hospital. In addition to the above a demonstrator of anatomy is appointed annually with a salary of £100 a year; and the medical tutor in like manner, with a salary of £100 a year. Both these officers are eligible for re-election.

All general students are required to perform the duties of clinical clerk and dresser during the last two years of their curriculum. Students of the third year and of subsequent years are also appointed to assist the physicians and surgeons in charge of the out-patients. There is a Hospital Medical Society, which meets regularly during the winter session.

A Maternity Department is attached to the hospital. There are special departments for Diseases of the Eye, the Ear, the Skin, and the Throat, in which clinical demonstrations are constantly given by the physicians and surgeons.

Scholarships, Prizes, &c.—Three Scholarships in Natural Science, each tenable for three years, and of the value of £60 the first year, £40 the second, and £20 the third year, and an Exhibition in Natural Science of the value of £20, tenable for one year. One of the scholarships and the exhibition are awarded, immediately before the commencement of each winter session, by open competitive examination. An extra Scholarship in Natural Science, tenable for three years, of the value of £60 the first year, £25 the second, and £15 the third, will also be awarded by open competition in October, 1880. A Scholarship in Anatomy of the annual value of £20, for students who have completed their second winter session; and a Scholarship in Pathology of £20, for students who have completed their third winter session. Examinations will be held and prizes awarded in the various classes of each year at the termination of both the summer and winter sessions. Two prosectors are annually appointed, who each receive £5 and a certificate for their services.

Fee to the hospital practice and lectures, 107 guineas in instalments, or 101 guineas in one sum; perpetual, 125 guineas in instalments, or 119 guineas in one sum. Fee to the hospital practice and lectures required for the examination in Dental Surgery by the College of Surgeons, 62½ guineas. Special entries can be made to courses of lectures or periods of hospital practice; no fee for registration.

Practitioners in the neighbourhood receive pupils to reside with them; information on this point may be obtained from the Dean.

MIDDLESEX HOSPITAL.—There is a special Cancer Department, affording accommodation for 33 in-patients, whose period of residence in the hospital is unlimited. Classes, open to all the students, are held for practical instruction in the microscopical examination of healthy and diseased tissues, and also in the application of bandages and other surgical apparatus. Students are allowed to take out to read at their own homes the books from the large and carefully selected medical library of the school. Two Entrance Scholarships, of the annual value of £25 and £20, and tenable for two years, are offered for competition at the commencement of the winter session. Two Broderip Scholarships, of the annual value of £30 and £20, tenable for two years, and a clinical prize (value ten guineas) are awarded to those students who pass the best examination at the bedside and the post-mortem room. The Murray medal and Scholarship, founded in connexion with the University of Aberdeen, is awarded every third year to a student of this hospital. The Governors' Prize of twenty guineas is also awarded annually to the student who shall most distinguish himself during his three years' curriculum. Valuable class prizes are also given, and ten resident clinical appointments

are annually awarded, after competitive examination, to students who have completed their education, and complied with the regulations of the school. The officers thus appointed—reside and board in the hospital free of expense. The college tutor assists all general students, especially those who are preparing for examination, free of charge; and his instruction is arranged with a view to avoid the necessity of students obtaining any private tuition apart from that of the Medical School. The fee for attendance on the hospital practice and lectures required by the Colleges of Physicians and Surgeons and by the Society of Apothecaries is £90, which may be paid by instalments.

The clinical clerk and dresser of the physician and surgeon of the week dine at the board-room table, free of charge. A limited number of general students are also allowed to dine at the board-room table. The paid offices of medical registrar, surgical registrar, resident medical officer, and demonstrator of anatomy are open to qualified men as they become vacant. All clinical clerkships and dresserships are awarded without fee.

ST. THOMAS'S HOSPITAL.—*Prizes and Appointments for the year 1880-81.*—For First-year's Students: Two Entrance Scholarships in Natural Science of the value of £100 and £60 respectively, open to all first-year's students, will be awarded during the first week in October, after an examination in Physics, Chemistry, and either Botany or Zoology at the option of the candidate; the William Tite Scholarship, the proceeds of £1000 Consols (£30 per annum), is awarded each year; also prizes of £20 and £10; summer, £15, £10, and £5. For Second-year's Students: The College Scholarship of 40 guineas, and the Musgrove Scholarship of 40 guineas, are awarded biennially to the student who shall take the highest place in the first-class list in the examinations at the end of the second winter session; they are tenable for two years, provided the holder obtains a place in the first class in the subsequent examinations: making the winter prizes, £42, £20, and £10; summer, £15, £10, and £5; with the dresserships and the clinical clerkships. For Third-year's students: Second Tenure of Scholarship £42, and prizes of £20, £15, and £10, and the Prosecutor's Prize of £5. Clinical clerks and dressers are selected according to merit. The Grainger Testimonial Prize of £20, awarded biennially to third- or fourth-year's students, for the best Physiological Essay, to be illustrated by preparations and dissections; the Cheselden Medal, for Surgery and Surgical Anatomy; and the Mead Medal, for Practical Medicine, are awarded annually to fourth-year's students. The Solly Medal, with a prize from 10 to 20 guineas, will be awarded biennially to a student of the third, fourth, fifth, or sixth year, for the best report of Surgical Cases. The Treasurer's Gold Medal, for general proficiency and good conduct, is awarded annually to a fourth-year's student. The house-physicians, house-surgeons, assistant house-physicians and surgeons, and resident accoucheur are chosen, from gentlemen who have obtained their professional diplomas, according to merit, and, with the dressers, are provided with rooms and commons. Two hospital registrars, at £100 per annum each, will be selected from gentlemen distinguished for merit.

The medical and surgical casualty out-patients are seen by the resident assistant-physician, the resident assistant-surgeon, the house-physicians, house-surgeons, and dressers, at from 12 to 1 o'clock daily. The Dissecting-room is open to the students from 9 A.M. to 5 P.M.

The fee to hospital practice and lectures may be paid in several ways:—1st. £125, paid on entrance. 2nd. £130, in two payments—£70 on entrance, and £60 at the beginning of next year. 3rd. Payment by three instalments—viz., of £60 at the beginning of the first year, £50 at the beginning of the second year, and £30 at the beginning of the third year, entitles a student after payment of the third instalment to an unlimited attendance. The fee for attendance on the general subjects required of students in Dental Surgery, is for the two years £55, or by instalments £50 for the first year and £10 for the second year. Regularly qualified medical practitioners are admitted to the hospital practice and to the lectures and library on payment of a fee of £12 10s. for unlimited attendance.

Special classes are held throughout the year for the Matriculation, Preliminary, Scientific, and 1st M.B. examinations of the University of London.

UNIVERSITY COLLEGE, LONDON.—The fees for lectures and hospital practice required by the College of Physicians

and Surgeons and the Society of Apothecaries during the student's entire course amount to 125 guineas if paid in one sum, or 130 guineas if paid by instalments—viz., first year 60 guineas, second year 50 guineas, third year 20 guineas.

Exhibitions, Prizes, &c.—Three Entrance Exhibitions, of the respective values of £100, £60, and £40 per annum, tenable for one year, are annually awarded, upon examination by printed papers, to gentlemen who are about to commence their first winter attendance in a medical school. The subjects of the examinations are—Chemistry, Physics, Botany, and Zoology. The next examination will take place at the College on September 28th and 29th. The Atkinson Morley Surgical Scholarship of £46, tenable for three years, is annually awarded to the student who, upon examination, is found to possess the greatest proficiency in the Theory and Practice of Surgery. The Sharpey Physiological Scholarship of about £70 per annum, tenable for three years, for proficiency in Biological Science. Filliter Exhibition: a prize of £30 is awarded annually, in July, to the most proficient student in the class of Pathological Anatomy. An Atchison Scholarship, value about £55 per annum, tenable for two years. Besides the above, gold and silver medals and other prizes are awarded in each class. The appointments of demonstrators of anatomy, of resident medical officer to the hospital, and of surgical registrar—all of which have emoluments attached to them—are almost invariably conferred upon students of the College. Physicians' assistants, house-surgeons, midwifery assistants, physicians' clerks, surgeons' dressers, ward clerks, and ophthalmic surgeons' assistants are selected from the pupils, without additional fees.

WESTMINSTER HOSPITAL.—The Hospital contains upwards of 200 beds. There are separate departments for Diseases of the Eye, Ear, Skin, Teeth, and Throat, and for Diseases of Women. The Anatomical Museum is constantly open to the students. There are also a Pathological Museum and a Materia Medica Museum.

In addition to the practice of the Hospital, pupils who enter for the whole period of medical education may attend, without further fee, the practice of the Royal Westminster Ophthalmic Hospital and of the Royal Hospital for Paralysis. Instruction in the Physical Examination of the Chest is given by Dr. Doukin, and in the use of the Laryngoscope by Dr. De Havilland Hall. Mr. R. Davy gives demonstrations in Orthopædic subjects.

A Curator of the Museum and Pathologist with a salary of fifty guineas, and a Medical and a Surgical Registrar are appointed annually, each with a salary of £40. A House-Physician, a House-Surgeon, and a Resident Obstetric Assistant are appointed for six months after examination, and are provided with rooms and commons. They each pay a deposit of £20 on appointment; but receive £25 at the expiration of the term if their duties have been performed satisfactorily. An Assistant House-Surgeon is appointed from among the senior students; he is provided with commons at the hospital table. Clinical Assistants to the Physicians and Surgeons, and to the officers in charge of special departments, are appointed from students of the fourth year. Every student must perform the duties of Clinical Clerk and Dresser.

Scholarships and Prizes.—The Fence and Houldsworth Entrance Scholarship, each £50 a year for two years; and two Entrance Scholarships, value £10, tenable for two years. Exhibition in Anatomy, Physiology, and Chemistry, value £10 10s., tenable for one year for first year's men. A Prize of £2 2s. by Mr. A. P. Gould, to the first year's student who is most regular and diligent in the Dissecting Room. Scholarship in Anatomy and Physiology, value £21, to student of second year (to be styled Assistant Demonstrator).—At the end of the third summer, Prizes of £5 each (books or instruments), in Clinical Medicine and Clinical Surgery. Frederick Bird Medal and Prize, value £15, to students who have completed their fourth winter; subjects of examination: Medicine, Midwifery, Diseases of Women and Children, and Pathology. Chadwick Prize for General Proficiency, £21 (books or instruments), to the most meritorious student or students of any year not exceeding the fifth. In most of the classes, Special Prizes are given by the Lecturers; and Certificates of Honour are awarded in each Class. Two Tutors assist and guide the students in their work, and hold Senior and Junior Classes.

WESTMINSTER HOSPITAL SCHOOL OF ANATOMY, PHYSIOLOGY, AND OPERATIVE SURGERY.—The School meets

the requirements of two distinct classes of students—i.e., 1. Advanced students and qualified practitioners, who may wish either to extend their knowledge of the foregoing subjects, or to recall to mind what they once knew and have since forgotten. 2. Beginners entering upon their medical studies by a short term of apprenticeship with a general practitioner. For the former, rapid advanced classes, complete in three months, but still thoroughly practical, will be provided; and for the latter, more elementary classes of six months' duration, also thoroughly practical. The Operations of Surgery are all performed on the dead body by the students.

GREAT NORTHERN HOSPITAL, Caledonian-road.—Consulting Surgeon: Frederick Le Gros Clark. Physicians: Drs. Cholmeley, Cook, Robert Bridges, and Burnet. Obstetric Physician: Dr. Gustavus C. P. Murray. Ophthalmic Surgeon: Mr. R. W. Lyell, F.R.C.S. Surgeons: Messrs. Gay, W. Adams, W. Spencer Watson, W. H. Cripps, J. Macready. Aural Surgeon: Mr. A. E. Cumberbatch. Dental Surgeon: Mr. Charles James Fox. Chloroformist: Mr. George Eastes. House-Surgeon: Mr. A. Wharry.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—Consulting Physicians: D. C. J. B. Williams, F.R.S., Dr. W. H. Walshe, Dr. R. Quain, F.R.S. Consulting Surgeon: Professor John Marshall, F.R.S. Physicians: Drs. J. E. Pollock, E. S. Thompson, C. T. Williams, R. D. Powell, J. Tatham, R. Thompson, and J. Fowler. Assistant-Physicians: Drs. B. Yeo, F. Roberts, T. H. Green, J. M. Bruce. Pathologist: Dr. Ewart. Dental Surgeon: Mr. C. J. Noble. Resident Medical Officer: Mr. F. J. Hicks. Secretary: Mr. H. Dobbin.—Three clinical assistants reside in the hospital for a period of six months. Pupils are admitted to the practice of the hospital: terms, £3 3s. for three months; perpetual £5 5s. The medical practice of the hospital is recognised by the University of London, the Apothecaries' Company, and the Army and Navy and India Medical Boards. The hospital contains 192 beds.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City-road, E.C.—Established 1814. 26 beds. Consulting Physicians: Drs. Herbert Davies and Horace Dobell. Physicians: Drs. G. Goddard Rogers, P. J. Hensley, Gilbert Smith, and D. W. Finlay. Assistant-Physicians: Drs. W. Murrell, H. S. Gabbett, and W. H. White. Consulting Surgeon: Mr. Jonathan Hutchinson. Surgeon: Mr. W. J. Walsham. House Physician: Mr. F. M. Pope. In-patients, 251; out-patients cases, 6065. This hospital has recently been enlarged by the addition of a very complete new out-patients' department, and wards for 14 additional in-patients. The office of House-Physician, which is tenable for one year, and for which a sum of £80 is voted in lieu of board, is filled up annually in October.

WEST LONDON HOSPITAL, Hammersmith-road, W.—60 beds. In-patients, 569; out-patients, 21,532. Consulting Physician: Dr. Henry Maudsley. Consulting Physician Accoucheur: Dr. W. O. Priestley. Consulting Surgeons: Messrs. Samuel Armstrong Lane and William Bird. Physicians: Drs. Goddard Rogers and Thorowgood. Physician for Diseases of Women: Dr. Wiltshire. Surgeons: Messrs. William F. Teevan and Alfred Cooper. Surgeon for Diseases of the Eye: Mr. B. J. Vernon. Assistant-Physicians: Drs. Fish, Milner Fothergill, and Donald W. C. Hood. Assistant-Surgeons: Messrs. C. B. Keetley, J. H. Morgan, and Mr. F. S. Edwards. Surgeon-Dentist: Mr. M. A. Smale. The practice of this hospital is open to all students and members of the medical profession. Gentlemen desirous of acting as clinical clerks or dressers can obtain all information on application at the hospital.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, 23, 24, and 25, Queen-square, Bloomsbury.—100 beds; 10 cots for children. The physicians attend every Monday, Tuesday, Wednesday, and Friday, at 2.30 P.M. In- and out-patients' practice and electrical-room treatment at that hour. Physicians: Drs. Ramskill, Radcliffe, Hughlings Jackson, and Buzzard. Physicians for out-patients: Drs. H. Charlton Bastian, W. R. Gowers, and Ferrier. Assistant-Physicians: Drs. Ormerod and Horrocks. Surgeon: W. Adams, F.R.C.S. Resident Medical Officer and Registrar: C. E. Beevor, M.B. Medical practitioners and students will be admitted on showing their cards.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—The hospital, founded in 1804, and considerably enlarged in

1876, now contains 100 beds for patients, which were occupied during last year by 1400 persons. The out-patients are yearly over 20,000. Operations are performed daily from half-past ten to one o'clock, and three surgeons attend on each day: Mr. Streetfield, Mr. Warren Tay, and Mr. Adams, on Monday and Thursday; Mr. Lawson, Mr. Couper, and Mr. Tweedy, on Tuesday and Friday; Mr. Wordsworth, Mr. Hulke, and Mr. Lyell, on Wednesday and Saturday. Students are admitted to the practice. Fees for six months, £3 3s.; perpetual, £5 5s.; with admission to demonstrations and lectures, to be given during the winter. Students of the hospital are eligible for the office of house-surgeon, or may be appointed clinical assistants.

ROYAL ORTHOPÆDIC HOSPITAL, 315, Oxford-street.—Surgeons: Messrs. B. E. Brodhurst, H. A. Reeves, Charles Read, and William E. Baskwill. House-Surgeon: Mr. H. F. Baker. Secretary: Mr. Maskell. Operations on Mondays at 2 P.M. The hospital is open to all legally qualified practitioners. Pupils are admitted to witness the practice of the hospital on the following terms: Six months, £3 3s.; twelve months, £5 5s.; perpetual, £10 10s.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL, King William-street, Charing-cross.—The hospital contains 50 beds; and the patients, who number 10,000 annually, are seen and operations performed daily at 1 o'clock. The following are the days of attendance of the surgeons: Mr. Power, Monday and Friday; Mr. Rouse, Monday and Friday; Mr. Macnamara, Tuesday and Thursday; Mr. Cowell, Wednesday and Saturday. The practice of the hospital is open to students. Fees for six months, £3 3s.; perpetual, £5 5s. Students of the hospital are eligible for the post of house-surgeon. Special Demonstrations and Lectures will be given during the session. Secretary, Mr. George C. Farrant.

NATIONAL DENTAL COLLEGE, Great Portland-street, W.—Consulting Physicians: Drs. B. W. Richardson and W. H. Broadbent. Consulting Surgeons: Messrs. Erichsen, Spencer Wells, and Christopher Heath. Consulting Dental Surgeon: Mr. J. Merryweather. Dental Surgeons: Messrs. F. Henri Weiss, Oakley Coles, G. J. Williams, A. F. Canton, H. T. K. Kempton, and Harry Rose. Assistant Dental Surgeons: Messrs. Willoughby G. Weiss, C. J. Noble, G. A. Williams, Thomas Gaddes, and W. R. Humby. House-Surgeon: R. D. Ashby.

LONDON SCHOOL OF DENTAL SURGERY, Leicester-square.—Lectures are delivered in winter on Mechanical Dentistry, by Dr. Walker, on Wednesdays, at 7 P.M.; on Metallurgy in its application to Dental Purposes, by Mr. Louis, on Tuesdays and Fridays, at 12 o'clock. In summer, Mr. Alfred Coleman, F.R.C.S. (Exam.), L.R.C.P., L.D.S., &c., lectures on Dental Surgery and Pathology; and Mr. C. S. Tomes, M.R.C.S., L.D.S., on Dental Anatomy and Physiology (Human and Comparative). General fee for special lectures required for the curriculum, £15 15s.—**DENTAL HOSPITAL OF LONDON** (in connexion with the above).—Surgeons: Messrs. Fox, Medwin, Gregson, Coleman, Moon, and Hill. Assistant-Surgeons: Messrs. Canton, Bartlett, Hepburn, Gibbings, Woodhouse, and Hutchinson. Dental House-Surgeon: Mr. R. G. Bradshaw. Assistant Dental House-Surgeon: Mr. Rees Price. Secretary: Captain H. B. Scoones. Fee for two years' hospital practice required by the curriculum, £15 15s.

SEAMEN'S HOSPITAL (late Dreadnought), Greenwich, S.E.—This institution is established for the relief of seamen of all nations. Casualties are received at all hours. Apartments are provided in the house of the surgeon for students and others who may be desirous of studying diseases incidental to tropical climates before entering the services or going abroad. Unusually good opportunities also exist for the practice of operative surgery. Honorary Consulting Physician: Dr. George Budd. Visiting Physicians: Dr. John Curnow, F.R.C.P., and Mr. R. C. Carrington, M.R.C.P. Honorary Consulting Surgeon: Mr. Geo. Busk, F.R.S. Visiting Surgeon: Mr. N. Davies-Colley. Surgeon: Mr. W. Johnson Smith. Secretary: Mr. Henry C. Burdett.

THE HOSPITAL FOR SICK CHILDREN, Great Ormond-street, Queen-square, W.C., and Cromwell House, Highgate.—Physicians: Drs. Dickinson, Gee, and W. B. Cheadle. Assistant-Physicians: Drs. R. J. Lee, O. Sturges, Thomas Barlow, D. B. Lees, and Robert Bridges. Surgeons, Mr. T. Smith, Mr. Howard Marsh, Mr. Edmund Owen, and Mr. J. H. Morgan. Surgeon-Dentist: Mr. A. Cartwright. Fee for three months' attendance, £3 3s.; perpetual, £5 5s.

Secretary: S. Whitford. There are now 104 beds in the hospital, Great Ormond-street, and 52 beds at the country branch; total 156. In-patients last year, 1119; out-patients, 12,407. The practice at the hospital has recently been thrown open gratuitously to the pupils of the different hospitals and medical schools of London on conditions which may be ascertained of the Secretary.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL.—Established 1752, for the reception of married and single women, the latter with their first child only. The hospital receives annually upwards of 500 women as in-patients, of whom three-fourths are primiparae, and upwards of 700 out-patients are attended. Of 1350 cases delivered since 1878, there were over 200 obstetric complications at birth or shortly after delivery. Physicians to the in-patients: Dr. Hope and Dr. Grigg. Physician to the out-patients: Dr. Champneys. The physicians attend daily, and give clinical instruction. Medical pupils are received to be trained in Midwifery. Fees: Ten guineas for six weeks, or fifteen guineas for twelve weeks. Monthly nurses and midwives are also received for training. Fees: Twelve guineas and twenty-five guineas respectively.

BRITISH LYING-IN HOSPITAL, Endell-street, St. Giles's, W.C.—Consulting Physician: Dr. Priestley. Consulting Surgeon: Mr. T. Spencer Wells. Physicians: Dr. Heywood Smith, Dr. Arthur Edis, and Dr. S. Fancourt Barnes. Matron: Miss Freeman. Secretary: Mr. Vincent Yardley. This institution receives women only as midwifery pupils. The pupils reside in the hospital, and attend the patients in-doors and within half a mile radius, under the direction of the matron and physicians. A course of lectures is also given by the physicians. The fee for the course of three months is ten guineas. Pupils that prove themselves competent receive a certificate signed by the physicians, enabling them to practise midwifery.

THE ROYAL HOSPITAL FOR CHILDREN AND WOMEN, Waterloo-bridge-road.—Instituted 1816. Consulting Physicians: Dr. Wilks, Dr. John Williams. Consulting Surgeon: Mr. J. Cooper Forster. Physicians: Drs. G. V. Poore, W. Park, G. Roper, and Edwin Burrell. Surgeon: Mr. Edwin Canton. Surgeon Dentist: Mr. W. Whitehouse. Resident Medical Officer: Mr. E. Overman Day. Secretary: Mr. R. G. Kestin. Advanced students in medicine, and such practitioners as may desire it, are permitted to attend the practice of this hospital gratis. If a certificate signifying such attendance be required, the sum of £5 5s. must be paid to the physicians and surgeons in ordinary conjointly.

VICTORIA HOSPITAL FOR CHILDREN, Chelsea, S.W., and Churchfields, Margate.—The Hospital contains 64 beds and 16 at the home at Margate; and has a large out-patient department (over 400 weekly). Physicians: Dr. Julian Evans and Dr. Ridge Jones. Physicians to the out-patients: Drs. Grigg, Pearson Irvine, Allchin, and Albert Venn. Surgeon: Mr. Cowell. Surgeons to the out-patients: Messrs. Churchill and Walter Pye. Dental Surgeon: Mr. Risdon. House-surgeon: Mr. Weyland Chaffey. Registrar: Dr. Beckingsale. Secretary: Captain W. C. Blount, R.N. Out-patients are seen daily as under:—Medical cases: Daily, except Saturday and Sunday, at 9 A.M.; also on Mondays and Thursdays at noon. Surgical cases: Daily, except Monday and Thursday, at 10 A.M. Dental cases: Saturdays at 9.30 A.M.

BELGRAVE HOSPITAL FOR CHILDREN, 79, Gloucester-street, S.W.—Twenty beds. Consulting Physician: Sir Wm. Gull. Consulting Surgeons: Mr. Wood and Mr. Brodhurst. Physicians: Dr. Hope and Dr. Ewart. Surgeons: Mr. Bennett and Mr. Dent. Surgeon Dentist: Mr. Payne. Pupils are admitted to the practice of the hospital upon producing a certificate of being duly registered as medical students.

EVELINA HOSPITAL FOR SICK CHILDREN, Southwark-bridge-road, S.E.—Consulting Physician: Dr. W. S. Playfair. Consulting Surgeon: Mr. Prescott Hewett. Physicians: Drs. E. Buchanan Baxter, F. Taylor, N. J. C. Tirard, James Goodhart. Surgeons: Messrs. W. Marrant Baker, H. G. Howse, and R. Clement Lucas. House-Surgeon: Mr. Henry Davy, M.B.

SCHOOL OF PHARMACY OF THE PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.—Chemistry and Pharmacy: Professor Redwood, Ph.D., F.C.S. Lectures are delivered on Monday, Tuesday, and Wednesday mornings at 9 o'clock. The course consists of sixty lectures. Two courses are given annually,

the first commencing on October 4th, 1880; and the second course on March 1st, 1881. The subjects of these lectures are—(1) Physics in relation to Chemistry and Pharmacy. (2) Inorganic Chemistry. (3) Organic Chemistry. Botany and Materia Medica: Professor Bentley, M.R.C.S. Eng., F.L.S. These lectures are delivered on Thursday, Friday, and Saturday mornings, at 9 o'clock. The first course commences on October 2nd, 1880; the second course on March 3rd, 1881. Practical Chemistry, directed by Professor Attfield, Ph.D., F.R.S., F.I.C., F.C.S., assisted by a Demonstrator, Dr. Alfred Senior, F.I.C., F.C.S., and an Assistant-Demonstrator, Mr. R. Dunstan, F.C.S., commences on Friday, October 1st, at 10 A.M. The laboratories are open from ten o'clock in the morning until five o'clock in the afternoon daily, except on Saturdays, when they are closed at two o'clock. Fees for ten months, according to hours of attendance, 12 to 25 guineas; for shorter terms in proportion.

SOUTH LONDON SCHOOL OF PHARMACY, 325, Kennington-road.—Managing Director, Dr. Muter. Daily lectures on Chemistry, Botany, Physics, Materia Medica, Pharmacy, Classics. Accommodation for 120 students. Apply to the Secretary, Mr. W. Baxter, Central Public Laboratory, Kennington-cross, London, S.E.

ENGLISH PROVINCIAL HOSPITALS AND MEDICAL SCHOOLS.

BATH ROYAL UNITED HOSPITAL.—Honorary Consulting Physicians: Drs. Falconer and Davies. Physicians: Drs. Goodridge, Coates, and Cole. Surgeons: Messrs. Gore, Stockwell, and Fowler. Dental Surgeon: Mr. Gaine. Pathological Registrar and Curator: Mr. H. Culliford Hopkins. The hospital contains 120 beds (in-patients last year 1064, out-patients 10,688), and is recognised by the General Medical Council, and licensed for dissection. It has also a good library and an excellent museum, containing a large number of interesting specimens both in pathology, human and comparative anatomy. Fees for attending the hospital practice, both medical and surgical: Six months, £5 5s.; twelve months, £10 10s.

Arrangements are being made by which pupils entering the hospital in October can be instructed in the subjects required for the new examination of the Royal College of Physicians, termed the First Professional Examination for the Licence, whereby they would be enabled to pass the examination during the year spent at the hospital; the subjects being Chemistry and Chemical Physics, Materia Medica and Pharmacy, Medical Botany, and Osteology.

QUEEN'S COLLEGE, BIRMINGHAM.—The Sands Cox Prize, of the value of £20, is given annually in the Medical Department. It is open to students who have completed their curriculum, and is awarded after examination in Medicine, Surgery, and Midwifery. The examination for this prize in 1881 will be held in the third week in March. Two Ingleby Scholarships will be awarded annually after examination in Obstetric Medicine and Surgery, and Diseases of Women and Children. These Scholarships are open to students who have completed the first two years of their curriculum in this College. One or more Sydenham Scholarships will be awarded annually of the value of thirty guineas each. The orphan sons of former students of the Birmingham Medical School shall have priority of election. No Sydenham Scholars shall be elected whose age exceeds twenty-three years on the day of election. The Scholarships shall be held for three years, subject to good behaviour. One or more Queen's Scholarships will be awarded annually of the value of thirty guineas. Medals and certificates of honour are awarded annually in each class after examination. Students of Queen's College are qualified to compete for all Scholarships, gold medals, and other prizes offered by the University of London, the Royal College of Surgeons, and the Apothecaries' Society.

THE GENERAL AND THE QUEEN'S HOSPITALS, BIRMINGHAM.—*The General Hospital.*—Consulting Physician: Dr. Fletcher. Consulting Surgeon: Mr. Crompton. Physicians: Drs. Russell, Wade, Foster, and Rickards. Surgeons: Messrs. Baker, Pemberton, Bartleet, Goodall, and Jolly. Obstetric Officer: Dr. Malins. Assistant-Physicians: Drs. Saundby and Simon. Assistant-Surgeons: Messrs. Archer and Chavasse.—*The Queen's Hospital.* Consulting Obstetric Surgeon: Mr. Berry. Physicians: Drs. Heslop, Sawyer

Carter, and Hunt. Surgeons: Messrs. West, Gamgee, Furneaux Jordan, and Wilders. Obstetric Surgeon: Mr. John Clay. Ophthalmic Surgeon: Mr. Priestley Smith. Dental Surgeon: Mr. Charles Sims.

The practices of these hospitals are amalgamated for the purposes of clinical instruction under the direction of the Birmingham Clinical Board. All students will be required to attend six months alternately at each hospital, excepting those who enter for six months only, who will be allowed to choose either hospital.

BRISTOL SCHOOL OF MEDICINE.—Students of Anatomy or Physiology who do not pay the composition fee of sixty guineas are required to pay a medical tutor's fee of two guineas per annum.

BRISTOL ROYAL INFIRMARY.—264 beds. Physicians: Drs. Spencer, Shingleton Smith, Waldo, and Shaw. Surgeons: Messrs. Board, Dowson, Prichard, Cross, and Greig Smith. Surgeon for the out-patients: Mr. Harsant. Medical Superintendent: Mr. Macintire. House-Physician: Dr. Watson. House-Surgeon: Dr. Lendon. Secretary: W. Trenerry. In-patients last year, 2330; out-patients last year, 22,768. Clinical clerkship, six months, five guineas; one year, eight guineas. Dressership, five guineas for each six months. Obstetric clerkship, three guineas for each three months. Special clinical instruction is given in Diseases of the Eye, Ear, and Throat, also in Diseases of Women. Several prizes, of considerable value, are open to competition among the students.

Fees.—Medical or Surgical Practice, six months, seven guineas; one year, twelve guineas; perpetual, twenty guineas. Medical and Surgical Practice together in one payment, one year, twenty guineas; perpetual, thirty-five guineas. The above fees include Clinical Lectures.

Pupils are entitled to attend the practice not only of their own physician or surgeon, but also that of all the physicians or surgeons. Surgical pupils, on acquiring the requisite experience, are permitted to dress all the out-patients, and also to reside in the house in weekly rotation, where they are in charge of all the casualties under the supervision of the house-surgeon. A Pathological Clerk, who performs all the post-mortem examinations, is appointed for three months from among the senior students. Practical Pharmacy at the laboratory and dispensary. The library contains about 3000 volumes, the museum over 3000 specimens.

BRISTOL GENERAL HOSPITAL.—154 beds. Physicians: Drs. Burder, Markham Skerrett, and Harrison. Physician-Accoucheur: Dr. Lawrence. Surgeons: Messrs. Lansdown, Atchley, Dobson, and Keall. Dentist: Mr. Parson. House-Surgeon: Mr. Pickering. Physician's Assistant: Mr. Bryden. Assistant House-Surgeon: Dr. Guy. Secretary: Lieutenant Fox. Clinical clerkship, six months, five guineas. Dressership, six months, five guineas. Obstetric clerkship, three months, three guineas. Special clinical instruction is given in Diseases of the Skin, Eye, Ear, and Throat, also in Diseases of Women, and in Dental Surgery. Several valuable scholarships are open to competition.

Fees.—Medical or Surgical Practice, six months, £6; twelve months, £10; perpetual, £20. The above fees include Clinical Lectures.

Pupils are entitled to attend the whole medical and surgical practice of the hospital. Dressers reside in the hospital in rotation, and free of expense, and attend all the casualties under the direction of the House-Surgeon. Instruction in Pharmacy is given in the hospital dispensary. There is a good library and also a museum, to both of which the students have access.

ADDENBROOKE'S HOSPITAL, CAMBRIDGE.—Clinical Lectures in Medicine and Surgery in connexion with the Cambridge Medical School are delivered at this hospital twice a week during the academic year; and practical instruction in Medicine and Surgery, in the wards and out-patient rooms, is given by the physicians and surgeons daily, during the vacations as well as term time. Instruction is also given in all the special modes of medical and surgical investigation. Clinical assistants and dressers are selected from students according to merit and without payment.

UNIVERSITY OF DURHAM COLLEGE OF MEDICINE, NEWCASTLE-UPON-TYNE.—*Scholarships, &c.*—A University of Durham Scholarship of the value of £25 a year for four years annually for proficiency in arts awarded to perpetual students in their first year only. The Dickinson Scholarship,

value £15 annually, for Medicine, Surgery, Midwifery, and Pathology. The Tulloch Scholarship, value £20 annually, for Anatomy, Physiology, and Chemistry. The Charlton Scholarship, value £35 annually, for Medicine. The Gibb Scholarship, value £25 annually, for Pathology. At the end of each session a Silver Medal and Certificate of Honour are awarded in each of the regular classes. An Assistant Curator of the Museum is annually appointed from among the senior students, and receives £12 as an honorarium. Two Assistant Demonstrators of Anatomy, two Assistant Physiologists, and two Pathological Assistants are also elected. Four resident dressers are chosen every six months, and are required to pay £10 10s. for board and residence.

Fees for Lectures.—Composition fee for all the lectures, qualifying for the Licence in Medicine and the Mastership in Surgery of the University of Durham, the Licence and Membership of the Royal College of Physicians, the Membership of the College of Surgeons, and the Licence of the Apothecaries' Society, and payable on entering to the first winter session, £52 10s. Separate courses of lectures, each £4 4s. Single course of Chemistry, £5 5s. The composition fee entitles the holder to attend the lectures on Botany, Chemistry, and Materia Medica, and to use the Museum of Materia Medica in the library of the College.

Hospital Practice.—This can be attended at the Newcastle Infirmary, which contains 230 beds. Midwifery, Diseases of the Eye, and Insanity can be specially studied. The Laboratories, Libraries, and Museums are open daily.

Fees for Hospital Practice.—Twelve months, £12 12s.; six months, £8 8s.; three months, £5 5s.; perpetual fee, £26 5s.; or, if paid by three instalments, first year, £12 12s.; second year, £10 10s.; third year, £6 6s. If paid by two instalments, first year, £14 14s.; second year, £12 12s. These fees are payable in advance.

GENERAL KENT AND CANTERBURY HOSPITAL.—Open for the reception of patients April 26th, 1793. 44,690 in-patients, and 76,742 out-patients, have been admitted since the hospital was open. The hospital contains 102 beds. Pupils of the staff are admitted to the practice of the hospital, and have the use of the library of the East Kent and Canterbury Medical Society for £7 7s. Operation day, Thursday, 11 A.M. Physicians: Drs. Alfred Lochee and Henry Alexander Gogarty. Consulting Surgeons: Mr. P. B. Hallows and Mr. James Reid. Surgeons: Messrs. Charles Holtum, Frank Wachter, Thomas Whitehead Reid, and John Greasley. Dentist: Mr. Robert J. Bell. House-Surgeon: Mr. William Shaw. Assistant House-Surgeon: Dr. A. H. Montfort. Secretary: Mr. Thomas Southee.

LEEDS SCHOOL OF MEDICINE.—Attendance at the lectures of this school will confer the same qualifications for examination as are obtained in the medical schools of London. The lectures on Chemistry, by Professor Thorpe, and that on Botany by Professor Miall, are delivered in connexion with Yorkshire College. The Hardwick Clinical Prize, value £10, is conferred annually upon the most deserving student who exhibits a satisfactory proficiency in Clinical Medicine. The Surgeons' Clinical Prizes, value respectively £8, £5, and £3, given by the surgeons to the hospital, are conferred annually on the most deserving students who exhibit proficiency in Clinical Surgery. In addition to the Silver Medal awarded in Medical Jurisprudence, there is a prize of £10 (Thorpe Prize), for which a special examination is annually held. Practical Surgery and Practical Physiology are taught in accordance with the regulations of the Royal College of Surgeons. In the Infirmary there are six clinical clerkships and eight dresserships. Four resident assistants are chosen from the senior students, board and residence free. There is a large Dispensary and a Fever Hospital in the town; both open to students attending the school.

Besides the lectures on Mental Diseases, clinical teaching is given by Dr. Major (the Medical Director), at the West Riding Lunatic Asylum.

The various courses at the Yorkshire College afford facilities for those studying arts and natural sciences.

LIVERPOOL ROYAL INFIRMARY SCHOOL OF MEDICINE.—Three house-surgeons and two house-physicians are elected every six months from pupils of the school who have obtained a qualification. Six dressers and six clinical clerks are elected quarterly; and post-mortem clerks for six weeks. Pupils of the infirmary are admitted to learn Pharmacy in

the dispensing department for six months. Two Scholarships of £21, held for two years. The hospital contains 300 beds; including 40 beds for the treatment of diseases of women. The Lock Hospital adjoining contains 60 beds.

Fees.—For six months' medical practice, five guineas; twelve months, six guineas; surgical, six guineas for six months, eight guineas for twelve months (this includes admission to the practice of the Lock Hospital adjoining the Infirmary); perpetual medical and surgical practice, thirty-two guineas.

LIVERPOOL NORTHERN HOSPITAL.—Physicians: Drs. Dickinson and Caton. Surgeons: Mr. Manifold, Mr. Chauncey Puzey, and Dr. Campbell. Dental Surgeon: Mr. J. B. Lloyd. House-Surgeon: Mr. W. E. L. Batty. House-Physician: Dr. D. M. Fraser. 145 beds. There is a special ward for the treatment of children. Clinical lectures are delivered by the physicians and surgeons during the summer and winter sessions. Clinical clerkships and dresserships are open to all the students without additional fee.

Fees for Hospital Practice and Clinical Lectures.—Perpetual, twenty-five guineas; one year, ten guineas; six months, seven guineas; three months, four guineas. Students can enter to the medical or surgical practice separately on payment of half the above fees. Practical pharmacy, three months fee, two guineas.

Attendance on the practice of this hospital qualifies for all the examining boards.

LIVERPOOL ROYAL SOUTHERN HOSPITAL.—Physicians: Drs. Cameron, Carter, and Williams. Surgeons: Messrs. Hamilton, Little, and Ransford. Senior House-Surgeon: Mr. Davies. Junior House-Surgeons: Mr. Welch and Mr. Chisholm. 200 beds. Clinical lectures are given by the physicians and surgeons during the winter and summer sessions. Clinical clerkships and dresserships open to all students. Special wards for accidents and diseases of children. Rooms for a limited number of resident students.

Fees for Hospital Practice and Clinical Lectures.—Perpetual, twenty-five guineas; one year, ten guineas; six months, seven guineas; three months, four guineas.

The practice of the hospital is recognised by all examining bodies.

NORFOLK AND NORWICH HOSPITAL.—120 beds. One year's attendance recognised by examining boards. *Fees:* For the physicians' practice, five guineas for six months; ten guineas, perpetual. For the surgeons' practice, including dressership, £10 for three months; £15 for six months; £20 for one year; £30 for two years; and £40 perpetual. Pupils, resident and non-resident. Physicians: Dr. Eade, Dr. Bateman, and Dr. Taylor. Surgeons: Mr. Cadge, Mr. Crosse, and Mr. Williams. Assistant-Surgeons: Dr. Beverley and Mr. Robinson. House-Surgeon: Mr. S. H. Burton.

NORTHAMPTON GENERAL INFIRMARY.—Established 1743; rebuilt 1793. In-patients, 1165; out-patients, 7380. Beds, 144. Physician: Dr. Buzzard. Surgeons: Messrs. Kirby Smith and G. H. Percival. House-Surgeon: Mr. A. H. Jones. Resident Medical Officer: Mr. E. J. Morley. Out-pupils are received and have every opportunity of acquiring a practical knowledge of their profession. Instruction is also given in Anatomy and Materia Medica, and Practical Pharmacy. Pupils' fees £25 per annum, or a perpetual fee of £50. The Infirmary is recognised by the examining boards.

OWENS COLLEGE (MANCHESTER ROYAL) SCHOOL OF MEDICINE.—This medical school is located in a large new building, which forms a part of Owens College. It is provided with a very large dissecting-room, physiological laboratory, private laboratories, and work-rooms, besides lecture-rooms, a museum, and a library. The departments of Anatomy, Physiology, and Chemistry are taught by professors who devote the whole of their time to the duties of their respective chairs. The more strictly practical departments of medical study are taught partly in the Medical School and partly in the Royal Infirmary, to which are attached a fever hospital, a lunatic asylum, and a convalescent home. Medical and surgical clinical classes are conducted in the Infirmary by the professors of medicine and surgery, and separate instruction is afforded in the elements of medical and surgical physical diagnosis, in obstetric medicine, ophthalmic surgery, and pathological anatomy, by the different members of the staff of the Medical School and Infirmary. The following scholarships and prizes are open to students of the Medical School:—1. A

Dauntsey Scholarship of the value of about £100 is offered annually for competition at the beginning of October to persons who have not been students in any Medical School in the United Kingdom and whose age does not then exceed twenty-five years. The subjects of examination are—(a) General and Comparative Anatomy; (b) Physiological Botany; (c) Chemistry; (d) Mathematics or Latin. 2. A Scholarship and Prizes are awarded at the end of each academic year to students of the first, second, and third year. 3. A Platt Physiological Scholarship of £50 a year for two years is offered annually to the student who, having studied for one entire session in the physiological laboratory of Owens College, has prosecuted the best original investigation in Physiology and has passed a satisfactory examination in Physiology. 4. Two Platt Exhibitions of the value of £20 each, to be competed for by first and second year's students in the class of Physiology. 5. A Dumville Surgical Prize of £20 is offered annually for proficiency in Clinical Surgery. 6. Medical and Surgical Clinical Prizes, each of the value of six guineas, are open to competition each year for the best reports (with comments) of cases which have occurred in the wards of the Infirmary.

SHEFFIELD SCHOOL OF MEDICINE.—The Infirmary contains 180 beds; a Museum of Pathology, Library, and Post-mortem Theatre, with microscopes and all the appliances for clinical research. Perpetual fee for attendance on all the lectures required by the Royal College of Surgeons and the Apothecaries' Hall, £45. Secretary, Mr. A. Jackson. A tutor's fee of £2 2s. is required from students entering for Anatomy and Physiology.

SHEFFIELD PUBLIC HOSPITAL AND DISPENSARY.—Physicians: Dr. H. J. Branson, Dr. Dyson, and Dr. Thomas. Surgeons: Dr. Keeling, Mr. Thorpe, and Mr. Pye-Smith. House-Surgeons: Messrs. C. C. Claremont, Morgan, and Dales. Number of beds, 105. In- and out-patients yearly about 30,000. A Physician and a Surgeon attend at the hospital daily. G. K. Thorpe, Hon. Secretary to the Staff.

HARTLEY INSTITUTION, Southampton.—In addition to preparations for the Preliminary Examination, instruction is given in Anatomy and Physiology, Zoology, Chemistry, Botany, Practical Chemistry, and in the use of the Microscope. The institution contains a fine collection of anatomical models, and a medical library. The Practice of the Royal Infirmary of Southampton is open to students.

The course of instruction is recognised by the Royal Colleges of Physicians and Surgeons of London for eighteen months of the four years of professional study required.

Fees £6 6s. per term, or £15 per annum, in advance, which entitle the student to twenty-eight hours' instruction per week, supplemented by the teaching in the School of Art Department of General Literature.

NORTH STAFFORDSHIRE INFIRMARY, Hartshill, Stoke-upon-Trent.—The new North Staffordshire Infirmary was opened in 1869, and is built on a new plan. It has accommodation for nearly 220 beds, including detached fever wards and children's hospital. In-patients last year 1587; out-patients, 9618. The Infirmary is recognised by the Court of Examiners of the Royal College of Surgeons of England, and students have great facilities for acquiring a practical knowledge of their profession.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—Medical Officers: Drs. Millington, Totherick, and Joseph Hunt; Messrs. Vincent Jackson, J. O'B. Kough, and F. E. Manby. Honorary Secretary to the Medical Committee: Dr. Joseph Hunt, Darlington Street, Wolverhampton. This Hospital contains 210 beds and a commodious semi-detached out-patient department. To the general wards a clinical-room is attached. Instruction is given in Chemistry, in Natural Philosophy, and in the Anatomy of the Dry Bones, Ligaments, Viscera, and Topographical Anatomy. The course of Practical Surgery includes the use of surgical apparatus, the performance of surgical operations, and the demonstration of Morbid Surgical Anatomy. In the Hospital the pupils are required to attend daily in the casualty-room, in the out-patient department, and in the wards, the instruction afforded being of a practical nature. The art of dispensing, the preparation of drugs and of pharmaceutical compounds, can also be learnt in the Hospital Dispensary and Laboratory. Operations are performed every Thursday at eleven o'clock, and practitioners are admitted. The prac-

tice of the Hospital is recognised by all the examining boards. Lectures are given in Elementary Medicine by Dr. Totherick and by Dr. Hunt, and in Elementary Surgery by Mr. V. Jackson.

Fees for Hospital Practice—For one year, £10 10s.; perpetual, £21. Some members of the honorary staff receive resident pupils.

YORK COUNTY HOSPITAL.—Established 1740; rebuilt 1851. 110 beds. In-patients, 753; out-patients, 4336. Physicians: Drs. G. Shann and W. Matterson. Consulting Surgeon: Mr. W. D. Husband. Surgeons: Messrs. R. Hewetson, W. H. Jalland, and F. Shann. House-Surgeon: Mr. F. H. Weekes. Secretary: Mr. R. Holtby.

SCOTTISH HOSPITALS AND MEDICAL SCHOOLS.

ROYAL INFIRMARY, EDINBURGH.—Beds are set apart for clinical instruction by the professors of the University of Edinburgh. Courses of Clinical Medicine and Surgery are also given by the ordinary physicians and surgeons. Special instruction is given in the medical department on Diseases of Women, Physical Diagnosis, &c., and in the surgical department on Diseases of the Eye. Separate wards are devoted to fever, venereal diseases, diseases of women, diseases of the eye, also to cases of incidental delirium or insanity. Post-mortem examinations are conducted in the Anatomical Theatre by the Pathologist, who also gives practical instruction in Pathological Anatomy and Histology. From and after the commencement of the Winter Session, 1880-81, the fees shall be as follows, viz.:—Perpetual ticket in one payment, £12; annual ticket, £6 6s.; six months, £4 4s.; three months, £2 2s. Separate payments amounting to £12 12s. entitle the student to a perpetual ticket. No fees are payable for any medical or surgical appointment. The appointments are as follows:—1. Resident physicians and surgeons are appointed, and live in the house free of charge. The appointment is for six months, but may be renewed at the end of that period by special recommendation. 2. Non-resident clinical clerks are appointed by the physicians and surgeons for such periods and under such conditions as they deem expedient. 3. Each surgeon appoints from four to nine dressers, the appointment being for six months. 4. Assistants in the Pathological department are appointed by the pathologist.

SCHOOL OF MEDICINE, EDINBURGH.—The lectures qualify for the University of Edinburgh and the other universities, the Royal Colleges of Physicians and Surgeons of Edinburgh, London, and Dublin, and the other medical boards.

In accordance with the statutes of the University of Edinburgh any four of the medical classes required for graduation, or two complete *Anni Medici*, may be attended in this school, each of which *Anni Medici* may be constituted by attendance on two of the six months' courses, or on one of these and two three months' courses. The regulations require that the fee for the class taken for graduation in Edinburgh be the same as that for the corresponding class in the University. The whole education required for graduation at the University of London may be taken in this School.

Fees.—For a first course of lectures, £3 5s.; for a second, £2 4s.; perpetual, £5 5s. To those who have already attended a first course in Edinburgh the perpetual fee is £2 4s. Practical Anatomy (six months' course), £3 3s.; course of demonstrations, £2 2s.; perpetual, £4 4s. Practical Anatomy with course of demonstrations, £4 4s. Practical Chemistry, £3 3s. Analytical Chemistry, £2 a month, £5 for three months, or £10 for six months. Practical Materia Medica, including Practical Pharmacy and Diseases of the Ear, each £2 2s. Vaccination, Diseases of Children, and Diseases of the Skin, each £1 1s. For summer courses of Clinical Surgery and Clinical Medicine, each £2 4s.; Practical Anatomy, including Anatomical Demonstrations, Operative Surgery, and Insanity, each £2 2s. The minimum cost of the education in this School of Medicine for the double qualification of Physician and Surgeon from the Royal Colleges of Physicians and Surgeons, including the fees for the joint examination, is £95; whilst the minimum cost for the single qualification of either Physician or Surgeon, including fee for examination, is £85.

The following order of study is recommended as a guide to the Student, though not enjoined:—First Year: Anatomy,

Practical Anatomy, Chemistry, Practical or Analytical Chemistry, Hospital. Second Year: Anatomy, Practical Anatomy, Physiology, Surgery, Materia Medica (the last either in this or the Third Year), Hospital. Third Year: Practice of Medicine, Clinical Surgery, Practical Anatomy, Practical Pharmacy, Clinical Medicine, Pathological Anatomy, Hospital. Fourth Year: Surgery, or Clinical Surgery, Midwifery and Diseases of Women and Children, Practice of Medicine or Clinical Medicine, Medical Jurisprudence, Practical Midwifery, Operative Surgery, Hospital.

Six Residencies will be completed for in 1881. Three of these, tenable for the following six Winter months, will be completed for in March, and three for the succeeding six Summer months in July, 1881.

EDINBURGH SCHOOL OF PHARMACY AND CHEMISTRY AND SCHOOL OF MEDICINE, Marshall-street, Nicholson-square.—The classes of this School will be resumed for the Winter Session on the 4th of October. Chemistry, Theoretical and Practical, Midwifery and Surgery. From the Dispensary attached to this Institution, Pharmacy, Practical and Theoretical, Practical Midwifery, and out-door Practice. Attendance at this Institution qualifies for the University of Edinburgh, and all other Licensing Boards. Tutorial Classes in all the branches of the Medical Curriculum. The Pharmaceutical Section of this School will open on Oct. 1st. Particulars of R. Urquhart, Secretary.

ANDERSON'S COLLEGE, GLASGOW.—A Dispensary is connected with Anderson's College; the object of which is to give gratuitous advice to the sick poor, and to visit them at their own homes when necessary. On Tuesdays and Thursdays, at 3 P.M., special advice is given on Diseases of Women and Children; on Wednesdays, at 3 P.M., advice is given on Diseases of the Skin; on Thursdays, at 1 P.M., advice is given on Diseases of the Ear; and on Fridays, at 3 P.M., advice is given on Diseases of the Eye. The number of visits paid to the sick poor at their own homes amounted to 6184. The visiting of these patients is entrusted to the students of the College, acting under the supervision of a specially-appointed Medical Officer, who visits along with the students, for the purpose of instructing them in the cases. Students of Anderson's College are admitted, free of charge, to the practice of this Dispensary; they are eligible for the various appointments common in such institutions; and, at the end of the session, they receive tickets of attendance, and certificates of home visitation. Fee for practice at Dental Hospital, required for L.D.S., £10 10s. Dental Anatomy: Mr. J. C. Morison, £2 2s. Dental Surgery: Mr. J. R. Brownlie, £2 2s. Mechanical Dentistry: Mr. W. S. Woodburn, L.D.S., £2 2s.

Medical Scholarships and Prizes.—The following Scholarships and Prizes are awarded:—1. A £12 Medical Scholarship, tenable for two years, and to be competed for in November, 1880, by students entering upon their second winter of medical study. 2. A £10 Medical Scholarship, tenable for two years, and to be competed for in November, 1880, by students entering upon their second winter of medical study. 3. £5 in prizes to students of the Senior Anatomy Class, at the close of the session. 4. £5 in prizes to students of the Physiology Class, at the close of the session. 5. £10 in prizes to students of the Junior Anatomy Class, at the close of the session. 6. £5 in prizes to students of the Chemistry Class, at the close of the session.

GLASGOW ROYAL INFIRMARY SCHOOL OF MEDICINE.—The winter session will open on October 27th. Courses of lectures are given on all the subjects required by the licensing bodies for qualification, and lectures are also given on Practical Physiology, Operative Surgery, Aural Surgery, Dental Surgery, and Diseases of the Eye. During summer, lectures on Insanity are given by Dr. A. Robertson, and the City Asylum under his charge is free to students of this school. Students have unusual facilities for the study of anatomy, the supply of subjects being practically unlimited.

Winter Session: Junior Anatomy, Anatomical Demonstrations, and Practical Anatomy, Mr. H. E. Clark; Physiology, Dr. Fleming; Surgery, Dr. H. C. Cameron; Materia Medica, Dr. John Dougall; Chemistry, John Clark, Ph.D.; Practice of Medicine, Dr. A. Wood-Smith.—Summer Session: Pathology, Dr. D. Foulis; Medical Jurisprudence, Dr. William Macewen; Practical Physiology, Dr. W. J. Fleming; Chemistry, John Clark, Ph.D.; Midwifery, Dr. James Stirton; Operative Surgery, Dr. H. C. Cameron; Aural Surgery, Dr. Johnstone Macfie; Anatomy, Mr. H. E. Clark; Dental Surgery, Dr. J. C. Woodburn;

Diseases of the Eye, Mr. H. E. Clark; Mental Diseases, Dr. Alex. Robertson.

Class Fees.—For each course, first session, £2 2s.; second session, and perpetual, £1 ls. Students who have attended a first course elsewhere can enter on the second course on payment of £1 ls. Anatomy: First winter session, £4 4s.; summer session, £1 ls.; second winter session, £4 4s.; afterwards the fee for lectures and practical anatomy is £1 ls. per session. Lectures on diseases of the ear, £1 ls.; with clinique to those not students of the hospital, £2 2s. Dental Dispensary free to students of the hospital; to others, £5; first year perpetual, £10. Lectures on the eye, £1 ls.

GLASGOW ROYAL INFIRMARY.—Number of beds, 532. In addition to the ordinary medical and surgical wards, there are separate wards for the treatment of venereal diseases and the diseases of women, whilst diseases of the eye, ear, throat, and teeth are specially treated at the dispensary. Courses of clinical medicine and surgery are given by the physicians and surgeons; instruction in pathological anatomy and histology is given by the pathologist.

Appointments.—There are five physicians' and five surgeons' assistants. These appointments can be held for six or twelve months, and are open to students who have passed all their examinations except the last, or to gentlemen who have a qualification in medicine or surgery. Clinical assistants, dressers, dispensary clerks, and pathological assistants are selected from the students without additional fee.

Fees for Hospital Practice and Clinical Lectures.—First year, £10 10s.; second year, £10 10s.; afterwards free. For six months, £6 6s.; three months, £4 4s. Students who have paid twenty guineas at another hospital for its perpetual ticket are admitted six months for £2 2s., or one year for £3 3s. Vaccination certificate, £1 ls.

GLASGOW HOSPITAL AND DISPENSARY FOR THE DISEASES OF THE EAR, 239, and 241, Buchanan-street.—Senior Consulting Physician: Dr. P. Stewart. Senior Consulting Surgeon: Dr. James Morton. Consulting Dental Surgeon: Dr. J. Cowan Woodburn. Consulting Surgeons for Throat Diseases: Dr. David Foulis, Dr. A. K. Irvine, Dr. A. L. Kelly, Dr. J. Gardiner. Aural Surgeon and Lecturer on Aural Surgery: Dr. James Patterson Cassells. Clinical Assistants: Messrs. Robertson and Violette.

This institution is supported by public and voluntary subscription, its object being the advancement of this special department of medical science by lectures and clinical teaching to students, and the gratuitous treatment of poor persons suffering from all forms of ear disease and deafness. Number of cases treated annually 3000.

The hospital, which contains 12 beds for indoor-patients, is always open for urgent cases. Hours of surgeons' visit, 3 p.m. daily; clinical teaching daily. Out-door patients are seen on Tuesdays, Wednesdays, Thursdays, and Fridays at 4 p.m., by Dr. Cassells and assistants, and operations and special demonstrations to students and practitioners on Saturdays from 11 to 1 p.m. during winter and summer sessions. John Mann, C.M., Secretary.

ABERDEEN ROYAL INFIRMARY.—Contains about 300 beds. Consulting Physician: Dr. A. Harvey. Physicians: Drs. J. W. F. Smith-Shand, R. Beveridge, Angus Fraser. Physicians' Assistant: Alfred Ireland. Surgeons: Messrs. W. Pirrie, A. Ogston, J. O. Will, and R. J. Garden. Surgeons' Assistant: John Ramage. Ophthalmic Surgeon: Dr. Alex. D. Davidson. Pathologist: Dr. James Rodger. Chloroformist: Dr. P. Blaikie Smith. Dental Surgeon: Mr. Williamson. Resident Superintendent and Apothecary: Dr. R. Rattray. Pathologist and Curator of Museum: Dr. J. Rodger. Treasurer and Secretary: Mr. W. Carnie.

IRISH HOSPITALS AND MEDICAL SCHOOLS.

QUEEN'S COLLEGE, CORK, SCHOOL OF MEDICINE.—The building is provided with a very large, well-ventilated dissecting-room, with physiological and toxicological laboratories, *materia medica*, anatomical and pathological museums, as well as a room for surgical and obstetrical instruments and appliances. There are well appointed physical and chemical laboratories, and a large natural history museum in the adjoining building; and part of the College ground is laid out as a botanical garden. The plant houses are now completed and well filled with plants, and are open to the students in the class of Botany.

Fees.—For Practical Anatomy, £3; for Practical Chemistry, £3 each course; for Anatomy and Physiology, £3 first course, and £2 for each subsequent course. Other medical classes, £2 first course, and £1 each subsequent course.—Eight scholarships (value about £30 each) as well as several exhibitions and class prizes are awarded every year.

Clinical instruction is given at the North and South Infirmarys, and at the Lying-in Hospital; students can also attend the Mercy General Hospital, the Maternity, the Children's Hospital, and the Eye and Ear Infirmary. Fee for clinical lectures and attendance at either the North or South Infirmary, eight guineas for twelve months; five guineas for six months. Clinical instruction can now be given to the students of Queen's College, Cork, by the resident medical superintendent of the Cork District Lunatic Asylum, which contains about 700 patients.

QUEEN'S COLLEGE, BELFAST.—*Fees:* Anatomy and Physiology, first course, £3; each subsequent course, £2. Anatomical Demonstrations and Practical Anatomy, each course £3. Practical Chemistry, £3. Other medical lectures: first course, £2; each subsequent course, £1.

SIR PATRICK DUN'S HOSPITAL, Dublin (in connexion with the School of Physic).—Consulting Physician: Dr. Alfred Hudson. Consulting Surgeon: Dr. William Colles. Physicians: Drs. John Mallet Purser, William Moore, Aquilla Smith, Edward B. Sinclair (Midwifery Physician). Surgeons: Drs. Benjamin G. McDowell, Edward H. Bennett, Thomas Evelyn Little, Richard G. Butcher (University Lecturer in Operative Surgery). The hospital is visited daily by each of the physicians and surgeons on duty.

The payment of £3 3s. to the hospital entitles any student to attend the clinic of the hospital for twelve months, and to attend the lectures delivered by Dr. R. G. Butcher, University Lecturer in Operative Surgery. Students who have taken out the degrees of Bachelor in Medicine and Master in Surgery in Trinity College are entitled to attend the hospital as perpetual free pupils.

Clinical Lectures are delivered in the hospital theatre, at ten o'clock on Mondays and Tuesdays. In addition to the hospital fee the payment of a fee of £9 9s. is required for the privilege of attending these lectures. Total fees for hospital and lectures for twelve months, £12 12s.

Sir Patrick Dun's Maternity.—Total fees for college students, £3 3s. Total fees for externs, £6 6s.

THE ADELAIDE MEDICAL AND SURGICAL HOSPITALS, Peter-street, Dublin.—Fee for nine months' Hospital attendance, £12 12s. Six months', £8 8s. Summer three months, £5 5s.

Three resident pupils are selected half-yearly. At the termination of the session prizes in Clinical Medicine and Surgery, in Obstetric Medicine, and in Ophthalmic Surgery, will be awarded. The certificates of attendance are recognised by all the Universities, Colleges, and Licensing Bodies in the United Kingdom. Physicians: Drs. Henry H. Head and James Little. Physician and Pathologist: Dr. Walter G. Smith. Surgeons: Dr. John K. Barton, Mr. Benjamin Wills Richardson, University Examiner in Descriptive Anatomy, Trinity College, Dublin, and Dr. Kendal Franks. Obstetric Surgeon: Richard Dancer Purefoy, M.B., F.R.C.S.I. Ophthalmic and Aural Surgeon: H. Rosborough Swanzy, M.A., M.B. Dental Surgeon: Dr. R. Theodore Stack. Consulting Obstetric Surgeon: Dr. Lombe Atthill.

LEDWICH SCHOOL OF SURGERY, Peter-street, Dublin.—This school is in a central situation and in the vicinity of four great medical and surgical hospitals, thus affording to the student the most ample opportunity of acquiring a thorough knowledge of the symptoms and treatment of disease. Demonstrators will be present in the dissecting room at all hours; and at the termination of the session prizes will be awarded to the best answers in each department. Applications to be made to T. P. Mason, 92, Harcourt-street, M. A. Ward, 9, Rathmines-road, joint-secretaries; or F. A. Nixon, 33, Harcourt-street, registrar.

RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS, North Brunswick-street, Dublin.—Physicians: Drs. J. T. Banks, B. G. McDowell, S. Gordon, and R. D. Lyons. Assistant Physician and Pathologist: Dr. Reuben J. Harvey. Consulting Obstetric Surgeon: Dr. Geo. H. Kidd. Surgeons: Drs. William Stokes, William Thomson, William Thornley Stoker, and Anthony H. Corley. Ophthalmic Surgeon: Dr. Charles E. Fitzgerald. Dental Surgeon: W. B. Pearsall, F.R.C.S.I.

These Hospitals contain 312 beds—110 for Surgical cases, 82 for Medical cases, and 120 for Fever and other epidemic diseases. During the past year 3183 patients were admitted; 19,612 out-patients were also treated; making in all 22,795 cases.

There will be a distinct Course of Lectures and Clinical Instruction in Fevers. Operations are performed on Monday and Wednesday mornings, except in cases of emergency. A Course of Practical Instruction in Ophthalmic Surgery will be given. Fee for the Certificate, three guineas. Practical Pharmacy is taught under the superintendence of the Apothecary of the Hospitals.

A Resident Surgeon is appointed every alternate year, receives a salary, and holds office for two years. Eight Resident Clinical Clerks are appointed each half-year, and provided with furnished apartments, fuel, &c., &c. These appointments are open not only to advanced students as formerly, but also to those who are qualified in Medicine or Surgery. The Dressers are selected from among the best qualified of the pupils, without the payment of additional fee.

THE RICHMOND LUNATIC ASYLUM, containing over 1000 patients, adjoining these Hospitals, affords every facility for the study of mental diseases.

Fees.—For the winter and summer session (nine months), £12 12s.; for the six winter months, £8 8s.; for the three summer months, £5 5s. Resident Clinical Clerks, 20 guineas for the winter session; 15 guineas for the summer term (from May to October, inclusive), including certificate of attendance, furnished apartments, fuel, light, attendance, &c.

ROTUNDA HOSPITALS, Rutland-square, Dublin.—Master: Lombe Athill, M.D. Assistant-Physicians: A. Duke, L.K. & Q.C.P., Andrew Horne, L.K. & Q.C.P. Pathologist: Dr. G. F. Duffey. This institution consists of two distinct hospitals—namely, the Lying-in Hospital, and the Auxiliary Hospital, for the reception of patients suffering from uterine and ovarian diseases. There is also a large extern maternity in connexion with the hospital, and a dispensary for diseases peculiar to women, which is open daily. Accommodation is provided for a limited number of intern pupils. Two courses of lectures are given yearly.

THE ANNUAL MEETING OF THE MEDICAL PRAYER UNION will be held at Freemasons' Tavern, Great Queen-street, on Tuesday, October 26th, at 7.30 P.M., when F. Le Gros Clark, Esq., F.R.S., will preside. The object of the Union is to promote Christian intercourse among members and students of the medical profession. At all the London hospitals there are branch associations, the meetings of which are held weekly or fortnightly. Further information may be obtained of the Hon. Secretary, 47, Endell-street, St. Giles's, W.C.

EDUCATIONAL VACCINATING STATIONS.

In order to provide for the granting of those special certificates of proficiency in vaccination which are required to be part of the medical qualification for entering into contracts for the performance of public vaccination, or for acting as deputy to a contractor, vaccination stations in London and the large towns are open, under certain specified conditions, for the purposes of teaching and examination. The public vaccinators officiating at these stations are authorised to give the required certificates of proficiency in vaccination to persons whom they have sufficiently instructed therein.

SUBSCRIPTION.

POST FREE TO ANY PART OF THE UNITED KINGDOM.

One Year.....	£1 12 6	Six Months	£0 16 3
To CHINA AND INDIA	One Year,	1 16 10	
To THE COLONIES AND UNITED STATES..	Ditto,	1 14 8	

Post Office Orders should be addressed to JOHN CROFT, THE LANCET Office, 423, Strand, London, and made payable at the Post Office, Charing-cross.

Notices of Births, Marriages, and Deaths are charged five shillings. Cheques to be crossed "London and Westminster Bank."

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements (on page 2), which not only affords a ready means of finding any notice, but is in itself an additional advertisement. Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance. Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET. Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed. Advertisements are now received at all Messrs. W. H. Smith and Sons' Railway Bookstalls throughout the United Kingdom. The postal arrangements relating to the distribution of THE LANCET will be considered from time to time in the interests of subscribers. Tables of Contents, with the Index of Advertisements, for each Number can be had on application to the Publisher.

Agent for the Advertising Department in France—J. ASTIER, 67, Rue Caumartin, Paris.

MEDICAL TEACHERS.

MR. EDW. B. AVELING, D.Sc., prepares for Preliminary Scientific, 1st and 2nd B.Sc. of London University.—Birkbeck Institution, 88, Camden-road, N.W.

MR. BECKTON, C.M. (1st Class), continues to prepare for the Preliminary Examination of the Royal College of Surgeons both for Membership and Fellowship, and of the Apothecaries' Hall. Boarders received.—2, Upper Bedford-place, Russell-square, W.C.

MR. L. BRYAN, B.A. Cantab., continues to prepare for the Preliminary Examinations of the Royal College of Surgeons and Apothecaries' Hall. Chambers central: 16, Clifford's-inn, E.C. (near the new Law Courts).

MR. THOMAS COOKE'S School of Anatomy, Physiology, and Operative Surgery is intended to meet the requirements of two distinct classes of Students—i. e.: (1) Advanced students and qualified practitioners, who may wish either to extend their knowledge of the foregoing subjects or to recall to mind what they once knew and have since forgotten; (2) beginners entering upon their medical studies by a short term of apprenticeship. For the former, rapid advanced classes, complete in three months, but still thoroughly practical, are provided; and for the latter, when required, more elementary classes of six months' duration. Private address: 16, Woburn place, Russell-square.

MR. A. H. DAWES, B.A. Lond., gives lessons privately, in class or by post, in preparation for the Primary Examinations of the London University, Royal College of Surgeons, and Apothecaries' Hall.—11, Burton-crescent, W.C.

MR. B. A. ELLIOTT, B.A. Lond., Emery Hill's Hospital, Rochester-row, S.W.; prepares Pupils for Matriculation and for the Preliminary Examinations.

DR. N. HEINEMANN, F.R.G.S., F.R.Hist.Soc., prepares for the Preliminary Examinations &c.—80, Upper Gloucester-place, Portman-square.

MR. G. HIND, F.R.C.S., continues his Classes as usual at 29, Newman-street, Oxford-street.

MR. THOMAS LYLE, B.A., F.R.Hist.S., prepares gentlemen for the Preliminary Examinations of the Apothecaries' Hall, the Royal College of Surgeons, and the University of London. A few Resident Pupils received.—Fern House, 48, Navarino-road, Hackney, E.

DR. A. C. MAYBURY, D.Sc. Lond., M.R.C.S., A.R.S.M., F.G.S., &c., reads with candidates for the Medical and Science Examinations of the University of London, Colleges of Physicians and Surgeons, Apothecaries' Hall, the Army and Navy Medical Services, &c.—23, Charlotte-street, Bedford-square, W.C.

MR. MURRAY, B.A., Arkton House, Wray-crescent, Tollington-park, N., prepares for the Preliminary Examination at the Royal College of Surgeons and Apothecaries' Hall, and the Matriculation at the University of London.

MR. J. H. ROSE, Ventnor College, Ventnor, receives a few Boarders for the Professions, Universities, &c. Term begins Sept. 15th.

MR. WM. NORRIE, M.A. &c., prepares students for the Medical Preliminary and Competitive Examinations generally. A few vacancies for Boarders.—9, Abercromby-place, Edinburgh.

DR. POWER holds classes for the various Competitive and Professional Examinations. Boarders received.—8, Red-lion-square, Holborn, W.C.

MR. B. H. SCANES SPICER, B.Sc. Lond. (Honours), prepares candidates for the Preliminary Scientific and First B.Sc.—186, Fulham-road, S.W.

MR. WAITE prepares Pupils for the Preliminary Examinations of the College of Surgeons and Apothecaries' Hall.—27, Chancery-lane.

MR. J. WOODLAND, F.L.S., Central School of Chemistry, 173, Marylebone-road, N.W., holds classes for the Examinations of the Royal College of Physicians.

DR. A. WRIGHT, Medical Preparatory College, Finchley, N., directs and supervises the professional studies of candidates for Medical Examinations.

TO CORRESPONDENTS.

OUR thanks are tendered to those gentlemen who have kindly supplied us with the requisite information given in this Students' Number of THE LANCET relative to the various medical examining bodies, hospitals, and medical schools of the United Kingdom.

In consequence of the present number being exclusively devoted to information especially interesting to students, reference to other subjects is necessarily postponed until next week.

Clinical Lecture.

ON

LARGE HEADS IN CHILDREN.

Delivered in St. Bartholomew's Hospital, June 4th, 1880,

By SAMUEL GEE, M.D., F.R.C.P. LOND.,

PHYSICIAN TO THE HOSPITAL.

GENTLEMEN,—There are two children in Mary ward who afford a good text for a lecture on big heads. Adults seldom or never consult you on account of the size of their heads, but children are very often brought for an opinion about their heads, which are thought to be too big, and to indicate water on the brain.

Much of what I have to say is taken from a paper on the "Shape of the Head, looked at from a medical point of view," which I published in the Hospital Reports for the year 1871.¹ The length of time which has since passed away gives me the advantage of sitting in judgment upon my own article, of correcting it, and of adding to it the results of a larger experience.

In the first place we must remember the rapid growth of the brain in childhood. During the first year the weight of the brain is more than doubled. "Sömmerring concluded that the brain reached its full size as early as the third year; the Wenzels and Sir W. Hamilton fixed the period about the seventh, and Tiedemann between the seventh and eighth."² This is not far from the truth. Hence the cranium or the brain-pan grows much more quickly than the face and the rest of the body; and hence the skull is often wrongly deemed to be unduly large, even in a perfectly healthy child.

When we are asked for an opinion about a big head, the first thing to do is to study, not its size, but its shape. Here we are helped by the cyrtometer, which will give us an exact outline of the head in any plane. Of the three chief planes of the skull—to wit, the horizontal plane and the two vertical planes (longitudinal and transverse),—the horizontal plane is certainly the least useful, and the longitudinal vertical plane the most useful. The latter plane passes through the tuber occipitale, sagittal suture, and glabella. It is the plane which anthropologists have chosen, as being the most important; so much so that Mr. Huxley deems it a disgrace in any ethnological collection to have a single skull which is not bisected thus.

Our cyrtometric tracing, then, passes from the deepest part of the nape of the neck just below the tuber occipitale, over the top of the head, to the deepest part of the bridge of the nose, a little above the canthus internus of the eyelids. The shape of a natural head, upon this plane, is that of an irregular pentagon with curved sides. Of the five sides of this pentagon, four belong wholly to the cranium, four increase in length as the cranium increases in size. The fifth side belongs partly to the face, and does not grow at the same rate as the other sides or as the cranium. This fifth side may be called the base line, inasmuch as it is a straight line joining the deepest part of the nape of the neck with the deepest part of the bridge of the nose, and corresponds roughly with the base of the skull. This base line, because it is somewhat of a constant, which does not change altogether with cranial changes, is most useful as a standard of comparison.

The greater number of big heads retain the pentagonal shape; some do not. I call the former long heads or dolichocephalæ, and the latter round heads or cyclocephalæ, for reasons which will appear hereafter.

I. Long Heads.—The cranium enlarges, but the base of the skull does not grow in proportion. The cranial sides of the pentagon lengthen, but very much more than the base line. The result is that the proportion between the greatest length of the cranium from before backwards and the base line is changed. I have measured a good many heads of healthy children under three years of age, and I find that the ratio between the greatest length of the cranium

and the base line is as six are to five; in other words, the cranium is about one fifth longer than the base. In these measurements, the greatest antero-posterior diameter must be taken parallel to the base line, an easy thing to do in the cyrtometric tracing. But even in a well-shapen head, the length of the cranium may be greater than the above-mentioned average; yet the ratio of greatest length to base line is seldom or never more than as five are to four—that is to say, that the cranium of a healthy head is never longer than the base line by more than one-fourth of the latter. If the cranium is longer than this, I call it dolichocephalic. This is not the meaning which Retzius, who invented the word, gave to it; nevertheless, I have ventured to change the meaning for medical purposes, and for reasons given in my paper in the Hospital Reports. The increased length of cranium shows itself before or behind, or in both directions. It is observed that the child's forehead is "overbuilt with most impending brows," or that the occiput is very protuberant, or that the head projects both back and front.

Let us now inquire into the state of things within a dolichocephalic skull. In my former paper I declared my belief that "dolichocephalus is always the result of increase in the solid contents of the skull, and not in its liquid contents. In other words, dolichocephalus indicates a big brain, and not water on the brain." I have now to say that this proposition is not universally true; on the contrary, dolichocephalus is only sometimes indicative of a big brain.

1. The big brain, in most cases, is naturally big. It does not afford any signs of disease, either during life by lesion of function, or after death by lesion of structure. The person has a head and brain too great for his body; that is all we have to say of him; but that is saying much, because it is saying that he is not suffering from the incurable disease which is always supposed in such cases.

2. The big brain is sometimes unnaturally big; it is said to be hypertrophous. Its functions during life are much impaired. Yet the naked eye cannot detect any structural changes after death. Some there are who affirm that hypertrophy of the brain is due to "diffuse interstitial hyperplasia of the neuroglia;" it would seem to be more agreeable with our present knowledge neither to affirm nor to deny. For hypertrophy of the brain is an uncommon disease. Few cases are on record, and for this reason I will narrate the following instance.

L. O.—, a boy two years and three-quarters old when seen for the first time. He was never able to walk; he did not cut his first tooth until he was ten months of age. When two years and a half old he became feverish, vomited, and screamed a great deal, and had fits, sometimes two a day, sometimes two a week. His mother's attention being drawn to his head, she noticed for the first time that it was large.

He was highly rickety—head, breast, and limbs all deformed. His head was much enlarged; but I have preserved no tracing of it, because at that time I did not use the cyrtometer. The fontanelle was widely open, not raised. Slight internal squint of right eye; no blindness; pupils equal. He seemed very dull, and cried fretfully. Two days afterwards he was convulsed, and died. Post-mortem appearances: Body not very thin; weight 17½ lb. Skull—fontanelle on a level with bones, about 1½ in. square. Recent black thrombi in posterior half of superior longitudinal sinus and of lateral sinuses. No flattening of convolutions. No excess of intracranial fluid anywhere. Brain weighed 59 oz. (more than one-fifth of the whole weight of the body). To the unaided eye its structure seemed natural; the grey matter was increased as much as the white; the corpora striata were very large. The consistency of the brain was natural, it was not toughened or hardened, and its specific gravity did not seem to be increased. The other organs were natural.

3. But in by far the greater number of dolichocephalæ which I have examined the brain has not been larger than natural. Wherefore, in such cases, the brain does not fill the skull, and the space between them is occupied by serum. The effusion is both external and internal; it seems to be passive, simply filling up what would otherwise be a vacuum. Nor are there any signs of pressure either upon the skull or the brain. In these particulars this kind of hydrocephalus, or water on the brain, differs altogether from the active hydrocephalus I shall have to speak of hereafter, which is ventricular or internal, which dilates the skull by equal pressure in all directions, into a sphere; and which also compresses the brain.

¹ St. Bartholomew's Hospital Reports, vol. vii., 1871.

² Quain's Anatomy, sixth edit., vol. ii., p. 430.

Now most, if not all, of these children are rickety; indeed, this kind of dolichocephalus and hydrocephalus is peculiar to rickets. The earliest writers upon rickets knew this; for details upon this point I may refer you to an article of mine upon rickets in the Hospital Reports for 1868.³ Let us see what explanations have been given of this rickety head. Van Swieten writes thus: "In rickety children the bones are softer, and the membranous spaces between the bones of the skull are wider than in healthy children; hence the whole fabric of the skull more easily yields to the distending encephalon, whence the reason also appears why an increased size of the head in rickety children is enumerated amongst the diagnostic signs of that disease. Now, if it be considered that the quantity and impetuosity of the humours towards the head are augmented from the magnitude of the arteries and jugular veins, it evidently appears why the bulk of the head may be increased on account of these three concurrent causes—the softness of the bones, the membranous state of a considerable part of the skull, and a copious afflux of blood to the part, whilst the rest of the body seems rather to decrease. And thus a disposition to a hydrocephalus arises, which sometimes accompanies the rickets, and sometimes is a consequence thereof."⁴ As who should say, the softened bones yield to the pressure of the blood within. Perhaps there may be a little truth in this explanation. Shaw holds that the cranium of rickets is only relatively big, and seems to be so because the face is actually smaller than natural on account of arrested growth. "In other words, in persons whose growth has been interrupted by rickets the face will appear extraordinarily diminutive, while the cranium will retain about its natural dimensions."⁵ Doubtless there is some truth in this explanation, but not the whole truth. In at least some rickety persons, if not in all, the cranium is extraordinarily big. In my former paper on the shape of the head I gave the measurements of a head which are decisive upon this point.⁶ Moreover, Shaw's explanation does not touch the hydrocephalus; if the cranium be of natural size why should it contain a great excess of serum, seeing that the brain also is of natural size?⁷ I will narrate a case in point. A boy three years old had never walked or talked. He had been very subject to convulsions since he was eight months old. He was very rickety, fontanelle more than an inch square, head very large. The body weighed 20½ lb., the brain 43½ oz., about its natural weight, yet it did not nearly fill the skull; there was much fluid in the arachnoid sac, the pia mater, and the ventricles. The brain seemed natural in all respects. I think we must end where we began, with the simple assertion that the skull in rickets is often enlarged so as to be greater than is necessary for the brain, and the excess of space is occupied by serum.

I will now speak of the manner in which the head is enlarged by inherited syphilis. It does so in two ways. First, the characteristic enlargement is due to extensive growth of the osteophytes described by Parrot.⁸ The cranial bones, especially the frontal and occipital bones, become greatly thickened, it may be as much as two or even three centimetres. The big head, such as it is, is indicative not of a cranial cavity larger than natural, but only of a thickened skull. Wherefore the enlargement of the head from this cause is never great. Secondly, the head of syphilitic children often possesses all the characters which I have just assigned to the rickety head, and I have always deemed these children to be both syphilitic and rickety, and have even gone so far as to believe that syphilis may be looked upon as a cause of rickets. But what shall we say to Parrot's doctrine that syphilis is not only a, but the, cause of rickets, that "syphilis leads of necessity to rickets, and that rickets, thus regarded, is not a pathological entity, but simply a period, a particular state, a form of hereditary syphilis, so much so that rickets can be no longer taken to include these syphilitic lesions of the bones, but, on the contrary, it is syphilis which includes rickets, and rickets thus sinks from the position which it has hitherto held into that of a simple syphilitic affection." If Parrot mean by rickets all that I have been accustomed to include under that name, I cannot accept his doctrine, I must even stoutly deny it. However, this question does not concern us here;

we are not discussing the nature of rickets, but the changes it produces in the size and shape of the skull.

II. *Round Heads.*—In this kind of big head the shape of the skull is fundamentally changed; it ceases to be a pentagon and becomes a segment of a circle. Cyclocephalus is the shape proper to ventricular hydrocephalus, a disease characterised by an active distension of the ventricles of the brain by serum, and a much more serious disease than the passive hydrocephalus I mentioned just now as being present in some rickety dolichocephalæ. Hydrocephalus does not produce a round head after the fontanelles are closed and the sutures well united. Acute ventricular effusion, occurring in tubercular or purulent meningitis, does not produce a round head, even when the fontanelle and sutures are not closed; the pressure, we may suppose, does not last long enough.

Another well-known effect of the active distension of the skull from within by fluid is the peculiar change in the position of the eyeballs with respect to the eyelids; a condition due to excessive obliquity and drawing-upwards of the orbital plates, and never associated with dolichocephalus.

Optic neuritis, going on to atrophy of the discs, is sometimes caused by hydrocephalus; especially when it sets in after the fontanelle has closed. When the head admits of distension, and becomes cyclocephalic, the optic neuritis is often absent.

Lastly, in extreme hydrocephalus, the head is sometimes seen to be translucent in a strong light, such as that of the sun.

Clinical Lecture

ON THE

RESULTS OF ANTISEPTIC OSTEOTOMY

FOR GENU VALGUM, VARUM, AND OTHER OSSEOUS DEFORMITIES OF THE LOWER LIMB.

By WILLIAM MACEWEN,

SURGEON, AND LECTURER ON CLINICAL SURGERY, ROYAL INFIRMARY, GLASGOW.

GENTLEMEN,—Having now operated on 557 limbs, belonging to 330 patients affected with various osseous deformities of the lower extremities, the opportunity is considered favourable for taking a retrospect of the results. Of these, 220 patients were affected with knock-knee, presenting 367 limbs for treatment. There were 64 patients who had 104 bow-legged limbs; 40 patients had 80 limbs affected with anterior or other tibial curves; and 6 patients had osseous ankylosis of joints—1 of hip and 5 of knee. Though 557 limbs were operated on, that does not indicate the number of osteotomies, as in many instances several osteotomies were performed on one limb. This happened in those cases of knock-knee which were complicated by other curves, such as anterior tibial; in such, the tibia and fibula were divided as well as the femur, making three osteotomies on one limb. In tibial curves of old standing, the tibia and fibula had to be divided at times in two places, making four osteotomies on one limb. Bow-leg, when aggravated, often required the tibia and fibula to be divided in two places and the femur in one—thus making five osteotomies on one limb, or ten on each patient. In this way there have been 835 osteotomies performed. Both limbs were operated on at once, and, with few exceptions, all the osseous incisions necessary for the correction of the deformity or deformities were proceeded with at one sitting: as many as ten osteotomies have been performed on one patient at once. The wounds leading to the bone are from three-quarters of an inch to an inch and a half; but even the smallest wound made cannot be looked upon, nor is it in any sense intended, to render the osseous incisions subcutaneous. The wounds enable the instrument to reach the bone; but as they are generally made more or

less obliquely, while the osteotome, after introduction, is turned transversely to the axis of the limb, there is an aperture on each side of the osteotome, leading from the external air directly to the interior of the bone. In rectifying anterior tibial curves wedges were removed by larger wounds than are required for simple osteotomy, the edges of the wounds being held aside by retractors, the purified air having free access to the interior of the bone during the whole operation. Not only so, but it is often the case, while rectifying the deformity, to hear the air whistling into the space between the divided osseous surfaces. They are therefore not subcutaneous osteotomies, but examples of compound fractures and incisions treated antiseptically. In one or two peculiar cases wedges were found on the opposite side from that on which the wound was made, and after being loosened, the deformity was rectified by displacement without removal of the wedge. In several other cases the curve was so great that the bones were divided in three or four places, the division being at very short distances from one another, thus causing what might be described as a compound comminuted incision and fracture.

After the osteotomy is finished the wounds are examined, and if there be a redundant supply of adipose tissue protruding above the level of the skin, it is carefully removed by a pair of scissors curved on the flat. If this be not attended to, the cellular tissue comes into direct contact with the protective plaster and granulations from above the level of the wound, which take a longer time to heal than the cellular tissue takes to vitalise. If the cellular tissue be removed, so as to form a concavity, the blood-clot fills this up, and a layer of blood-clot is thus formed between the protective plaster and the cellular tissue. When the wound is large, a few catgut stitches are introduced.

All the cases are dressed and put up in splints before removing the patient from the table. The temperature is taken night and morning, and if it be found normal and there is no discharge, no pain or discomfort, the dressings are not touched until the end of a fortnight, when they are removed, and the wounds are found healed. This, as we are aware, is what happens in most cases. The blood-clot between the lips of the wound is seen to be vitalised and covered by a delicate, almost transparent, layer of epithelium, which however quickly becomes opaque by exposure to the light. With the exception of eight cases, all these 557 limbs and 835 osteotomies healed by vitalisation of blood-clot without the production of a drop of pus. In seven of the eight cases which suppurated there was a distinct known cause for the pus production; thus in three instances a bruising and laceration of the soft parts occurred during the operations. In one case a layer of muscle became caught between the cut surfaces of the tibia and was severely rubbed during the adjustment of the bone. The fifth and sixth cases were due to irritation set up by pressure in one and by the splint in another; the seventh may be also attributed to over-pressure of the limb, which became twisted by the patient's own actions. In the eighth case there was no cause which was apparent for the pus production. In each of these cases the temperature indicated the impending mischief, as it was above normal, and put us on our guard. The amount of pus in these cases varied from a few drachms up to a number of ounces, necessitating frequent dressings. But all of them, with one exception, did well; they ultimately recovered perfectly, their convalescence not being much protracted beyond the ordinary time. The exception is the one mentioned as the seventh case—a lad who was affected with bow-leg, who, on the second night, during the nurse's temporary absence, rose from bed and fell, his splints and bandages becoming shifted and his foot twisted. This circumstance was concealed. On the morning following the occurrence the foot and leg were found twisted, the toes were cold and livid, and ultimately became gangrenous. After amputation of the limb the lad gradually recovered, and is now strong and healthy. There is no doubt but that this result was the consequence of his own act, coupled with the subsequent concealment of the fact; attention was only drawn to the mishap ten hours after, when the foot was found twisted. The true cause was only confessed long after.

Of those who have been operated on, three died *after* the operation, but none have died *from* the operation. One died from pneumonia contracted prior to the operation, one from tubercular meningitis, and one from diphtheria.

The first was a patient whose friends stipulated for her that she should be operated on when admitted, as her situa-

tion was only to be kept open for a limited period. This was acceded to. She was seventeen years of age, and when first seen by me she had the aspect of a girl in fair general health. In answer to inquiries regarding her health, she stated that she was well and was prepared and anxious for the operation. She had a slight herpetic eruption on the lips at the right angle of the mouth, which she attributed to cold. The operation was proceeded with. She took chloroform badly, and several times during the operation it had to be temporarily suspended, owing to fits of coughing. On recovering from the anæsthetic, several rusty-coloured sputa were expectorated, and on examining the lungs there was a very slight dulness with a very fine vesicular crepitation detected over the left base posteriorly. It then transpired that she had come from Ireland two days previously, and had remained on deck during the whole of a December night, that next day she had had a feeling of cold and shivering, but being desirous to have the operation performed, and also thinking that the shivering was a trifle in itself, she did not mention it in giving her history on the morning of the operation. The expectoration during the operation day continued to be streaked with blood, the colour deepening as the time advanced; the catching pneumonic cough set in towards the second morning, and the herpetic eruption at the side of the mouth spread. In short, the pneumonia developed and passed through its various stages, the left lung in its middle and lower lobes being involved, and death ensued at the end of two weeks. The wound on the right limb healed by vitalisation of blood-clot. That on the left at first closed, but, probably owing to the movement consequent on the application of poultices to the lung, it afterwards suppurated, but before death it had again almost healed.

It is evident that the operation had been performed just at the outset of what ultimately proved to be severe pneumonia. Had the operation been postponed for twenty-four hours, the symptoms would have manifested themselves, and the operation would not have been performed.

The second case was that of a lad nineteen years of age, who had been subject to periodical attacks of head symptoms since childhood; he, however, had been free from them for about six months prior to the operation. Osteotomy was performed in both limbs; the wounds healed by vitalisation of blood-clot, and the dressings were removed on the tenth day. Up till this time everything had gone well; the wounds were healed, the limbs straight, and he had suffered no pain. On the eleventh day he was somewhat duller than usual, and seemed slightly stupid. At night he was restless, confused, and turned about. On the next day he was a little better, but his pulse at times was very slow, and at others quick, the change occurring from one to the other within a few hours. His temperature remained about normal; once or twice it was subnormal. Vomiting set in early, and was persistent. His pupils were widely dilated, the eyes assuming a wakeful, brilliant appearance; occasionally he squinted. On the third day from the commencement of the symptoms he became slightly delirious, but could be made to answer questions. On the fifteenth day after the operation he died. His parents and friends stated that the symptoms which he exhibited on this occasion were quite similar to those which characterised his former attacks, and so satisfied were they of this that no amount of persuasion could induce them to grant a post-mortem examination. Though no autopsy was obtained, Dr. Foulis, the pathologist, and Dr. Clark, the lecturer on anatomy, examined the external appearances of the body. They saw that the wounds on the limbs were firmly healed, and that there was no abnormal appearance of the limbs.

It is evident that this lad died from a head affection, most likely of a tubercular nature, originating during childhood and continuing to manifest itself up to adolescent life. About the same time a patient fifteen years of age was met with who passed through almost identical attacks prior to any operation having been performed on him. He had had such attacks from early childhood, coming on at intervals of six or nine months. This lad was operated on for double knock-knee. He had no attacks during convalescence, and recovered perfectly. It is now nine months since he was operated on, and he has been in good health ever since.

The third fatal case was that of a girl aged seven years, who had a single osteotomy performed on her. She took diphtheria on the seventh day and died from the diphtheria on the twelfth day. The diphtheritic membrane stretched down the bifurcation of the trachea. Notwithstanding the

high temperature consequent on the diphtheritic pains the wound healed by vitalisation of blood-clot. There was not a drop of pus formed. A post-mortem examination was conducted by Dr. Foulis, and the only post-mortem specimen of an osteotomy was thus obtained. This specimen will again be alluded to, but meantime allow me to point out that the incision in the bone has been made exactly as it is described theoretically.

These are the only three cases of death after osteotomy, and not one of these can be traced to the operation, all of them being attributable to extraneous causes.

In order that you may fully understand the foregoing remarks and appreciate the results, it is necessary to supply the following information regarding the constitutional condition of the patients operated on. In my earlier osteotomies the strong and healthy were selected, with few exceptions. It soon became apparent, however, that if this selection were continued it would exclude many patients, and among them those whose limbs most required straightening and those who would derive most benefit from the results. It was seen that in those who were comparatively healthy the operation was followed by little or no constitutional disturbance. It then became a question whether the state of the system in those persons who were weak and reduced would have such an influence on the wounds as to induce phenomena in them which might reflect on the system and negative the performance of the operation.

The way was at first very carefully felt in this direction, step by step; and the solution arrived at, deduced from abundant data, is that an antiseptic osteotomy can be performed in the weak and enfeebled with impunity; their constitutional state does not suffer from the operation; neither does it affect the healing of the osseous incision, further than by requiring a little longer time for producing firm union. Not only so, but we can go a step further, and state that the result of the operation and straightening of the limbs has been to improve and strengthen the constitution. The patients are able to walk freely about, the physical deformity has been removed, and thereby a load has been lifted from their minds, which in itself conduces to improved health. Thus none were rejected on account of their weakness constitutionally, the only test being the state of the bones. If the period of *ramollissement* had passed and the bones had become firm the operation was proceeded with. On several occasions the patients were so weak that there was considerable hesitation about administering an anæsthetic. Many have been carried to the wards by their friends, as they were unable to walk except by the aid of crutches, and that for a very short distance; they have been operated on, and have gone out on their feet, and have become useful members of society, able to work for their own maintenance.

It is further interesting to note that a number have passed through attacks of acute diseases after the operation had been performed, such as scarlet fever, measles, and diphtheria, and that while these diseases have run their ordinary course, the wounds have not been affected by them: they have healed in the same way as the others did, by vitalization of blood-clot without the production of pus. In a case of scarlet fever the rash appeared on the third day after the operation, the fever ran its usual course, desquamation followed, and a portion of skin from the neighbourhood of the wound shed, taking along with it an almost transparent layer of delicate epithelium from the surface of the blood-clot, leaving, however, the latter covered.

When osteotomy is viewed in relation to other methods proposed for the relief of such deformities of the lower extremities, it is seen to be at least as safe, much more speedy in its action, and a great deal more certain in its results. Besides, most of the other methods are applicable alone to children, their effects for the most part being inappreciable when applied to adolescent life; whereas osteotomy has had excellent results up to thirty-six years of age. As to the time required from the date of the operation till the patient is able to walk without artificial support, this varies, but ten weeks may be taken as the average: six weeks in splints; the next fortnight walking with crutches, and the following one learning to walk without them. This time is for the adult; children are able to go about much sooner. The result which is looked for and obtained is a straight limb with complete movement of the joints.

A surgeon said not long ago that he did not care about such operations, as they were required principally among the poorer classes. This is no doubt true, and the truth of the assertion enhances the value of the operation; for it is among

the working classes that the struggle for existence is keenest, and where such physical malformations are not only looked upon as unseemly, but are actually barriers to many occupations. But though poor in purse, there is no class of patients richer in gratitude. The contrast between the dejected frightened look with which these patients enter the wards, bundling themselves into corners out of view, and the manner in which they walk about on their return from the home with happy faces, betokening the consciousness of having gained a lease of new existence, is indeed a pleasant sight. The patient feels that you have taken away a reproach from him; you have enabled him to earn his bread, and you have placed him on a footing of equality with his fellows; and the man for whom you bring about such things cannot easily forget. But the mere fact that you can take up a deformed fellow, and by a few touches and a little after-care set him straight, ought in itself to be a recompense.

CASES OF RUBEOLA.

By J. L. ERSKINE, M.D.,

BRIGADE-SURGEON, ARMY MEDICAL DEPARTMENT.

IN THE LANCET of March 13th a case of rubeola was published by Dr. Dyce Duckworth, who prefaced his account of it with the remark that, "as doubt still exists in the minds of many experienced practitioners respecting the peculiar and specific nature of rubeola, it seems desirable to place on record all cases that may be met with." Accepting this dictum, and also the remark of Professor Thomas of Leipzig, in Ziemssen's *Encyclopædia of Medicine* (vol. ii., p. 136), that "epidemics of rubeola have not yet been sufficiently studied," I am induced to publish a short account of two cases of rubeola seen by me.

CASE 1.—On April 3rd, at 10 A.M., I was called to see a young gentleman, aged seventeen years, who stated that though he had gone to bed quite well the previous night, he had not slept well, feeling restless and feverish. On examination, I found the face, tonsils, and uvula somewhat swollen, the two latter dusky-coloured, and the cervical glands enlarged. The face, neck, and arms were covered with a pale-red rash, slightly raised above the skin. The spots of eruption were generally round or oval, though some of the patches were irregular in outline, more especially on the neck, where the eruption was thickest. The tongue was clean; bowels regular; no thirst. Eyes suffused, but no lachrymation. A gentle aperient saline mixture was ordered every four hours, and the patient allowed out of bed.

April 4th.—The rash has extended downwards over the trunk and behind as far as the nates. Eyes suffused; face is less swollen, but cervical glands more so; tonsils and uvula much as yesterday; tongue clean; appetite good; bowels opened; urine clear. Temperature 99° 8'. Continue the saline mixture, with an astringent gargle. Evening: The rash has now extended to feet.

5th.—Less swelling of throat and glands of neck. Eyes not so suffused. Temperature 99° 4'. Continue medicine and gargle.

6th.—Eruption fading. Omit medicine, continue gargle.

7th.—Eruption disappeared from face and extremities, but still faintly seen on the body. Temperature yesterday and to-day normal.

8th.—On calling found that my patient, feeling quite well, had gone out to walk.

Remarks.—On first seeing this case I inferred it was a case of measles, the eruption being modified in consequence of the patient having suffered from a severe attack of measles eight months previously; further, the eruption was so dissimilar in appearance to what I had previously seen in a few cases of rubeola seventeen years ago at Malta, and in one case at Aldershot eight years ago, at which periods the eruption more resembled that seen in scarlatina than measles. I was, however, led to believe it was a case of rubeola from the sudden appearance of the eruption in one previously in good health after exposure to contagion, the patient stating that he must have caught the disease from a boy in the school the day prior to his own attack, the boy having been covered with an eruption.

On the second day of the illness Dr. Dunlop, who had seen and described in THE LANCET of Sept. 30th, 1871,

an epidemic of rubeola, saw the patient with me, and again on a subsequent occasion, and agreed that it was undoubtedly a case of rubeola. This view has been since confirmed from three other cases having occurred in the same school, and three more in the practice of an acquaintance at St. Helier's, who described the course and appearance of the disease much as I found it.

Contrary to Dr. Dunlop's experience in the epidemic recorded by him, there were no petechial spots on uvula or tonsils, nor red flushes over the joints. The constitutional disturbance was all throughout very slight, and the appetite so good that the stomach was never deranged from being overloaded, and a purge was ordered on the 7th. I did not examine the urine for albumen. It was clear throughout the illness.

CASE 2.—On April 14th S. N.—, a girl of eleven years of age, got wet during the afternoon; she was then quite well. At 9 P.M., feeling cold, she was sitting near the fire, when her mother observed her face swollen and covered with a red rash. On examination this was observed to cover the whole body. At 11 P.M., the mother said, the girl was very feverish.

April 15th.—I saw the girl at 12 A.M. She was reported to have slept well. The face was swollen, eyes suffused, no lachrymation, cervical glands enlarged, uvula and tonsils slightly swollen, of a dusky red, and covered with petechial spots, but no complaint was made of the throat feeling sore. The face, body, and limbs were covered with a rose-red rash, more resembling scarlatina than measles. There was little fever. Temperature 99.2°. No thirst or headache, tongue slightly furred, urine clear. A purge of compound jalap powder was ordered, and a diuretic saline mixture to be taken every four hours.

16th.—Bowels not relieved, repeated the purge, and continued the mixture. Temperature 99°. Face less swollen, throat, cervical glands, and eruption as yesterday, eyes suffused, no lachrymation. Evening—bowels moved.

17th.—Eruption almost disappeared; throat less swollen; petechial spots fainter in colour; still some swelling of face, with slight suffusion of the eyes; cervical glands less swollen; temperature normal; urine depositing urates on standing. Continue saline mixture thrice daily.

18th.—Eruption gone; no swelling of face; throat only very slightly congested; no petechial spots; slight swelling of cervical glands. Omit medicine.

19th.—Quite well.

Remarks.—This case did not much resemble the other. The eruption was quite different in appearance, being rose red and more diffused, not patchy. According to the mother's statement, it was all over the body when she looked about 9.30 P.M. on the evening of attack; whilst it gradually spread downwards in the first case recorded; the eruption seemed to fade equally generally over the body. Then the petechial spots on the throat were well marked in this, but absent in the first case. There was little constitutional disturbance. No exposure to contagion could be made out.

Jersey.

HUMAN AND ANIMAL VARIOLÆ: A STUDY IN COMPARATIVE PATHOLOGY.

By GEORGE FLEMING, F.R.C.V.S.,
ARMY VETERINARY INSPECTOR.

(Concluded from page 375.)

GOAT-POX.

THE goat has a variola of its own, which possesses as special and distinctive characters as that of the animals I have already described, and is entirely independent of infection from other species. In some countries this *Variola caprina* is apparently unknown, in others it is extremely rare, while in at least one country, Norway, it is a frequent, if not a continuous disorder, amongst the caprine population. I am not aware if it has ever been witnessed in this country, where goats are so few in number; for Germany, Bollinger says it is so infrequent, that in the course of twenty or thirty years scarcely half a dozen cases are recorded. He is of opinion that goats receive the disease either from cattle affected with vaccinia, or sheep suffering from sheep-pox.

But he admits that though now and again the same form of variola is witnessed in cows and goats, yet that the latter, as a rule, remained exempt from the disease when confined in the same stable with infected cows, and that the inoculation of goats generally yielded negative results. In order to prove that goats may be infected with sheep-pox, he gives the following on the authority of Prietzsch: "In a stable in which sheep suffering from sheep-pox were confined, three goats were simultaneously attacked with the disease, the eruption being the same as in the sheep. Upon the udder were numerous pisiform variolæ in the form of hard, flattened papules, with a trifling amount of lymph; papules were also distributed over the body, being more numerous upon the hind extremities than the abdomen. Marked symptoms of fever were also present, with inappetence, swollen lips, and a somewhat profuse muco-purulent discharge from the nostrils. In fourteen days convalescence was established. Two other goats were inoculated on the ear with the virus of sheep-pox; a single pustule formed at the seat of inoculation, and the animals did not afterwards take sheep-pox."

That there is no relationship, so far as origin is concerned, between sheep-pox and goat-pox, nor yet, for that matter, human variola, is evident if we look at a country where the latter is all but unknown, and the former is not seen. From 1864 to 1876 inclusive, sheep-pox has been reported only twice in Norway; in 1865 there were two cases, and in 1868 fifteen cases, all due to foreign importation. According to Hansen, the official veterinary surgeon in central Norway,¹ in 1867-68-69, and 1874 and 1875, extensive outbreaks of goat-pox were observed; and according, also, to the official veterinary statistics in 1865, eleven cases of the so-called "water-pock" (*Variola serosæ*), and in 1868 four cases of common goat-pox were recorded in South Norway. Many cases which escape the notice of the Government veterinary surgeons are supposed to occur. In 1871 Dr. Cæsar Boeck, of Christiana, was on a botanical excursion in South Norway, and in July, in Thelemarken, he saw a drove of cows and goats being driven from the woods into their huts. The cattle were quite healthy, but about forty of the goats were affected with a variolous eruption on the udder and teats, as well as about the mouth. In some there were merely deep dark-coloured sores remaining, in others—the majority—there were seen thick brownish crusts, about the size of a pea, on the mouth, udder, and adjoining parts; while in a few the disease was so recent that, with the crusts, there were also observed pustules from the size of a lentil to that of a pea. From inquiry and examination, Boeck was of opinion that the exanthem had been more or less general over the body, and that there had been fever and resulting emaciation. The milk secretion had been almost diminished, and the fluid itself was drawn with difficulty and pain. None had died, and no other animals had, so far as the shepherdess knew, been in contact with her drove. The cows were fifty in number, and none of them showed the least trace of disease. The cows and goats were milked indiscriminately by three women, whose hands were not washed from the commencement to the end of the operation; so that there was abundant opportunity for transmission of the disease from the goats to the cows, had the latter been susceptible; while the constant association of the two species, particularly in the closely-packed sheds, gave every facility for infection through the atmosphere, if this could have taken place. Experimental inoculation would have been tried, but no good lymph could then be found. The epizooty appeared in the spring, among the four-year-old goats which had been kept during the winter by themselves in small sheds. When they joined the other goats at a later period, the outbreak became general in a short time. Flocks of sheep associated with the goats without any disease resulting in them. Sheep-pox—a very fatal disease—had never been seen in that part of Norway. Boeck, who contributes his observations to the *Deutsche Zeitschrift für Thiermedizin* for December, 1879, alludes to Veterinary Surgeon Hansen's observations with regard to the outbreaks in 1867-68-69, and 1874-75, in *Gudbrandsdalen*. In the first year the malady appeared in August in two different flocks, numbering 170 goats, attacking without exception the males, kids, and those in milk. In the males the eruption was sparse, and limited to some pock pustules on the scrotum. (In the following year, the exan-

¹ Gudbrandsdalen d. h. Gudbrandsthal.

them on the males extended to the inner surface of the thighs.²) Hansen was called in when 13 of the 170 goats had died, and nearly all the others were affected. On examination of two of the carcasses, he found the eruption all over the body, and pustules and ulcerations on the mucous membrane of the stomach and intestines, as is often witnessed in malignant sheep-pox. The origin of the outbreak could not be accounted for, the goats not having been in contact with strange animals, and there was no similar disorder prevailing among other creatures. "I have practised in Gudbrandsdalen," says Hansen, "for twenty years, and I have never seen either cow or sheep-pox." In the goat-sheds were 60 cows and 80 sheep, but these remained healthy.

In June, 1868, in another district of the same parish, Hansen was sent for to see a herd of goats, and of 114 eighty-four had an eruption of pocks on the udder and teats; twenty were severely affected, and, in addition to the pocks on the lacteal apparatus, there were many on the inner side of the thighs and on various parts of the abdomen, some of them having ruptured and left large sores. The pain was so acute during milking that the animals cried and struggled, and had to be held. The milk was rather viscid and mixed with blood. The disease existed in all stages among the animals, from red spots to shedding crusts and the formation of cicatrices. The outbreak had only occurred eight days previously. Thirty animals were yet unaffected, and these were isolated. The neighbouring goat-farms were free from the malady, and Hansen could not account for its presence on this farm; but as it was only distant about half a mile (Norwegian) from the place where it prevailed the previous year, it might have been conveyed from there. In July all the goats on the farm had been infected; at the commencement of August goat-pox had nearly disappeared, and during the entire period of the outbreak the cattle there and in the neighbourhood had continued healthy.

On August 17th of the same year, Hansen was again called to attend upon goats at another place, not far from the last, where there were seventy-four goats, only thirteen of which were free from goat-pox. Twelve were severely affected, and three were so ill that they could not follow the others. The pocks on the udder, teats, and thighs could be studied from the first or inflammatory stage to the crust-forming and cicatrising period, the cicatrices being distinguishable from ordinary scars by their light hue. The diminished secretion of milk and emaciation were very marked, though the malady was not so fatal as in the previous year. On four neighbouring farms the disease also appeared among the goats.

When the disease once appeared in a flock it spread rapidly, and spared neither young nor old, male or female; those goats giving most milk having, however, the mildest attack, and the males having the pock-pustules most developed on the inside of the thighs. The contagium might have been conveyed to these farms by direct contact with the first infected farm, or, as was more probable, through the medium of servants and children. In the following month a number of other farms were visited by the goat-pox. Some of the goats had phlegmonous inflammation of the udder as a consequence of the disease, and had to be killed.

In 1869 two herds of goats were attacked, but timely and careful treatment having been adopted the results were not so serious. The milch goats were the worst attacked, and the mortality was greatest in the largest herds. The total number of cases for this year was 129. In the four succeeding years Hansen did not know of any outbreaks.

In July, 1874, goat-pox broke out in two different districts, one and a-half Norway miles apart, three farms being visited by it—one with 150 goats, another with 120, and the third with 60. All of these were more or less affected. The disease first commenced with slight fever; then followed efflorescence, subsequently the eruption on the udder and teats of small vesicles the size of a pea, and which soon became converted into pustules. Not unfrequently suppurating furunculi formed, and the whole udder was involved.

In some instances pocks appeared on the lips. Towards the end of August, there were reported 580 cases of goat-pox in the two localities. On the neighbouring goat-farms the disease was not seen. There was no evidence that it could

be communicated to mankind, though it appeared not improbable that mankind could convey it from one flock of goats to another. Ten deaths only were reported. In 1875 there were 200 cases. Hansen states that altogether there were 1300 goats attacked, with from 25 to 30 deaths—about 2 per cent. The incubative period appeared to be short, certainly not longer than a week, while the duration of the disease was from two to three weeks in the severer cases. The pock cicatrices were more or less stellate-shaped. Immunity was very rare indeed, nearly every goat exposed to infection taking the disease. The outbreaks always occurred during the summer months, and the epizooty did not extend beyond Hansen's official district. Boeck and others competent to judge had no doubt whatever that the disease was variola. Neither sheep nor cattle, notwithstanding their constant exposure to infection and being crowded with the goats in close sheds, became affected. Human variola was not present in the district during the years when goat-pox prevailed.

I have entered into these details with regard to goat-pox, because they support in the strongest manner the position I have taken up with respect to variola in man and animals, and prove that, inasmuch as we have shown that there is a cow-pox, a horse-pox, and a sheep-pox, there is also a goat-pox, independent of the variolæ of other animals.

SWINE-POX.

Swine-pox is not a very rare disorder, and though I fail to find more than one outbreak recorded as occurring—though outbreaks may be frequent—in this country, yet I have been assured by a very observant and competent veterinary surgeon that he saw a large number of swine suffering from the disorder in Kent. No small-pox or cow-pox was present in the locality. Like the ovine variola, the *Variola suilla* is a general eruptive disease, the symptoms being pretty constant in their development, and resembling those of sheep-pox. After the febrile phenomena, which are often very intense and continue for some days, there appear on the back, abdomen, chest, neck, head, and inner surface of the thighs, petechiæ, which soon become papules. Towards the sixth day there are vesicles, and about the ninth or tenth day pustules; the contents begin to desiccate and form crusts, which are eliminated in a few days, leaving a well-defined cicatrix. The eruption appears discrete and confluent, the disease being benignant or malignant, regular or irregular, according to the form it assumes. Young pigs are most susceptible, and the mortality often reaches twenty or twenty-five per cent. The malady is very contagious, and its course and complications, as well as infectiousness, are very closely analogous to those of sheep-pox. One attack protects from another. Felix (*Recueil de Méd. Vétérinaire*) describes an outbreak which prevailed among swine in the Dordogne department, during four years; and Rueling, Greve, Spinola, Viborg, Eisel, Hering, and other competent veterinary authorities have studied swine-pox at various times. Gerlach has experimentally proved that the disease can be transmitted to sheep, and the sheep-pox to pigs. Cases of accidental transmission from sheep have been recorded. Bollinger mentions that some young swine were attacked after being lodged in a pen where diseased sheep had been located some months previously, and these pigs communicated their malady to others which had not been in the shed in question. But that there is no genetic relationship between swine and sheep-pox is again proved by reference to Denmark, where the latter does not exist, and where, nevertheless, swine-pox is sometimes prevalent, as in 1878, when it appeared in several localities in Jutland, according to the veterinary sanitary reports of that kingdom. The same evidence could be given with respect to other countries. Accidental transmission of human small-pox to pigs has been recorded now and again, and that this transmission may take place I do not deny; but it certainly does not prove that swine-pox is dependent for its origin on small-pox. The former occurs where the latter is not present, as in Denmark, and small-pox may rage for years in districts where pigs are numerous, and the latter show no signs of variola. In the Würtemberg reports for 1877 mention is made of the prevalence of the "wild" or *Wasserpocken* (*Variola serosa*) among suckling swine. These pocks soon burst, and their contents mixing with the milk, were ingested by the young pigs in the act of sucking. These had in a short time a yellowish-brown eruption, first about the eyes and nose, and then over the entire body. When the eruption was noticed early, and

² From this it will be seen that the male goats are as liable to the goat-pox as the females. It is the same with the rams associating with flocks of sheep, and which suffer as much as the ewes; and it would be the same with bulls or bullocks, did they consort with cows affected with cow-pox. Sex makes no difference.

the young pigs were then removed from the sows, the consequences were not so serious; but when the exanthem extended over the entire body, they quickly died. Bathing them in bran water or camomile tea was supposed to have cured a good number. No mention is made of small-pox among people. In 1878, according to the *Veterinary Journal* (vol. vii., p. 210), there was a serious outbreak of swine-pox in many localities in the Hernals and Baden districts. It first appeared among swine of Hungarian origin imported from Odenburg, and from them was communicated to the native herds. The mortality was unusually great. The conditions attending the appearance, course, and termination of the disease were precisely analogous to those which obtain in sheep-pox, and the veterinary sanitary measures in force for the latter were adopted successfully for the swine-pox. No mention is made of sheep-pox, cow-pox, or small-pox prevailing at the time.

DOG-POX.

In the dog, variola has been observed and described by many authorities, and is, in fact, a comparatively well-known disease to veterinarians. It chiefly attacks young dogs, though old ones are not exempted, and one attack affords immunity from others. *Variola canina* commences, as in other animals, with fever, which continues for two or three days, and is then followed by the appearance over a large surface of the body, though rarely on the back or sides, of red points resembling flea-bites, which in a very short time are the seat of papules, and then of vesicles. The contents of these become purulent, and finally dry into a crust, which, being shed, leaves a marked cicatrix. In the dog, as in the sheep, goat, and pig, the disease does not always maintain the same form; it is sometimes epizootic, and is benignant or malignant. Young dogs nearly always succumb, and a necropsy often reveals the presence of variolous pustules on the mucous membrane of the respiratory and digestive organs. The disease does not appear to be very infectious, though it is contagious and inoculable. It appears to be communicable to mankind, for Bösenroth³ saw the disease affecting dogs around the nose, face, eyes, and back, and the attendant became infected. The dog does not appear to be very susceptible to the variolæ of other animals, nor yet to that of man. I cannot find but one instance mentioned in which small-pox was communicated to this creature, notwithstanding its very close association with mankind and consequent exposure to infection. Greve inoculated eight dogs with the matter of human small-pox, and three of them became covered with pustules and died. Vaccination only develops insignificant bullæ containing pus; scarcely any "pit" remains.

I am not aware that variola has ever been observed in the cat.

CAMEL-POX.

The camel has long been known to suffer from variola. Agnelli, in 1850, observed an outbreak among camels in Algeria, the symptoms of which were like those of cow-pox. When the Arabs were inoculated with the lymph they were protected from small-pox. Masson⁴ makes similar remarks with regard to the camel in India.

Hares and rabbits are said to have a form of variola, especially in North Germany, and which sometimes is very malignant.

VARIOLA GALLINARUM, ANSERUM, ETC.

Fowls have also their variola, according to the reports of various observers, published during many years. Bollinger has investigated what was supposed to be variola in a poultry yard at Zurich, but found it to be a contagious epithelioma, chiefly localised upon the head. But what appears to be a true variola has often been studied in fowls, as the loss it caused was very great, and its contagiousness caused it to be wide-spread. In these outbreaks the birds were dull and feverish; the feathers stood erect; the wings and tail were pendulous, and an eruption of pustules appeared on the head, neck, and inner surface of the wings and thighs. In the turkey they appeared as citron-tinted vesicles, surrounded by a red areola. In from twelve to fifteen days after their development these pustules became crusted, the fever disappeared, and health gradually returned. In geese the pustules on the neck not unfrequently increased in size and formed abscesses; the feathers were shed, pieces of skin even became detached, and the resulting lesions were

so serious that death was not an unusual termination. The disease was very contagious.

In the official report on the sanitary condition of the domesticated animals in Belgium during 1878, I find that Government Veterinary Surgeon Dejonghe, of Wyngene, describes this variola of poultry. It prevailed as an intense enzooty during the last half of 1878, frequently attacking all the fowls on a farm, and being most prevalent in low damp situations. It was markedly contagious, or rather infectious, and the prevailing winds had apparently some influence in its dissemination. Young birds suffered most severely, and bad food aggravated its severity. The earliest observed symptoms were erect plumage (horripilation), complete indifference, *malaise*, and general prostration, anorexia, great thirst, ardent craving for cold water, and rapid emaciation. There appeared on the skin and visible mucous membranes numerous small nodules, which were soon transformed into pustules. Most frequently these pustules soon after their appearance ruptured, fetid matter escaped, and only superficial sores remained; these generally cicatrised rapidly. Where the skin was thick, cicatrices, often deep, remained. On the respiratory mucous membrane the pustular eruption caused an abundant formation of muco-pus, which sometimes caused death by obstructing the air-passages. Generally, however, a fatal termination seemed to be due to debility, septicæmia, or pyæmia. In birds which survived, complete recovery did not take place for a long time.

NEW INSTRUMENT FOR ESTIMATING ASTIGMATISM.

By TEMPEST ANDERSON, M.D., B.Sc.,
FELLOW OF UNIVERSITY COLLEGE, LONDON.

ASTIGMATISM is that condition of the eye in which the refraction is different in different meridians of the eye, owing to the refractive media not being perfectly symmetrical. An eye with a cornea shaped like the bowl of a spoon, instead of like a portion of a sphere, would be astigmatic. The instrument exhibited by the author at the meeting of the British Association at Swansea has the following advantages. 1. The observations and measurements are made by the observer, and are entirely independent of the patient's sensations. 2. An image thrown on the retina being used as an object, the error arising from the vessels or optic nerve being before or behind the retina is avoided. 3. The refraction and accommodation of the observer does not affect the result. It is only necessary that he should be able to see whether certain lines are sharply defined. A lamp (A, in the engraving) is provided with a

A, Lamp. B, Condensing lens and wires. K, Graduated bar.
C, Convex lens. D, Mirror. E, Disc of lenses.

condensing lens, which has a screen of radiating wires (B) across its front, thus giving a bright field with black lines. This slides on a graduated bar (K), at the other end of which is a convex lens (C). It is better to have two of these of different powers, 4 and 10 dioptres being convenient. Close to the lens, and at an angle of 45° to it, is a plane silvered mirror (D), which reflects the rays at right angles to their

³ Magazin für Thierheilkunde, 1860, p. 341.

⁴ Narrative of a Journey to Khelat, Trans. of Med. and Phys. Soc. of Bombay, 1840, p. 214.

former path. The instrument is held so that this pencil of rays enter the observed eye, and when the screen is at the proper distance an image of it is formed on the retina. The mirror has its centre left unsilvered, and has an ordinary disc of lenses (E) behind it, to render the retina and the image on it visible to the observer by the ordinary direct method. The bar is so graduated that when an image of the whole or part of the screen is sharp on the retina, the figure opposite the screen expresses the refractive error of the meridian by which the image is produced. Hence, if the image of the whole screen is seen to be equally sharp, the eye is known to be not astigmatic, and the graduation gives the number of dioptics by which it is myopic or hypermetropic. If the lines be not all sharp at once, then the most distant point at which any of them is distinct gives the refraction of the meridian of minimum refraction, and the point at which that at right angles to the former is distinct gives that of maximum refraction. The least of these gives the spherical element of the correcting spectacle required, and their difference that of the cylindrical element. The meridian of maximum refraction is that in which the line appears distinct when the screen is at the greatest distance. If the cylindrical lens be convex its axis must be in this meridian; if concave, then at right angles to it. The makers are Cook and Sons, York.

Stonegate, York.

ON THE USE OF OLIVE OIL IN LARGE DOSES FOR SOFTENING AND CAUSING THE EASY EXPULSION OF BILIARY CALCULI.

By RODERICK KENNEDY, M.D.,
QUEEN'S COLLEGE, KINGSTON, CANADA.

It is scarcely a matter of doubt that the means resorted to for solution and expulsion of biliary calculi have hitherto proved slow and uncertain in their operation. Systematic writers, as a rule, do not attach a great deal of weight to the value of the so-called solvents. Not a few incline to the view that remedies of this kind are practically all but inert. Others assert in plain terms that medicines having these powers do not exist. Chloroform alone, or with ether, in the hands of some, is said to have removed these bodies, but this mode does not seem to have come into general use, probably because it requires time, and the proof of success is inferential. A simple medicine, readily available in practice, and having the power of softening and expelling biliary calculi, it will be admitted has hitherto been a desideratum. Such a medicine I have, during the past year, used in a variety of cases, and, I am happy to say, always with complete success. In every instance in which the calculi were proved, or presumed, to have been the cause of periodic suffering, these bodies were promptly and painlessly expelled in larger or smaller numbers by the use of large doses of olive oil. In some instances lately, where the patients did not exhibit symptoms of such acute suffering as are more commonly witnessed, but where obstruction to proper flow of bile was evident, I had recourse to this remedy, and in these cases also have been rewarded with similar surprising and satisfactory results.

A brief notice of a few cases illustrating the effects of the means used may prove to be not without interest.

Robert C—, of Adolphustown, an elderly farmer, had for some years been subject to hepatic disorder, attended with the occasional passing of gall-stones. The intervals between the passing of the bodies had gradually become more brief, and lately the paroxysms, always characterised by intense suffering, had come on at intervals of about a week with great regularity. I found the patient anæmic, sallow, and very much exhausted. The usual remedies for the gradual solution of the stones had been tried, but radical relief not being obtained, mitigation of the intense suffering was what, previous to my being sent for, had been principally aimed at. I ordered six ounces of the oil to be taken at bedtime, to be followed in the morning by a full dose of castor oil. No motion of the bowels was obtained till next evening, after the administration of an enema. Twelve hours after taking the oil, the patient began to com-

plain of a good deal of nausea and faintness, and for several hours there was considerable restlessness, and constant apprehension that the usual paroxysm was about to come on, but no acute pain. In the evening the enema was followed by several copious motions, each containing numbers of softened gall-stones, amounting in all to not fewer than two hundred, varying as to size from a large hickory-nut to a small pea, of a pale yellowish-green colour, semi-transparent, soft, easily broken up, and of a great variety of shapes. The patient had a good night's rest, and expressed himself in the morning as feeling very much better, and enjoyed a light breakfast. After the lapse of two days, the paroxysms threatening to return, I ordered the oil to be repeated two nights in succession. The expulsion of a quantity of slimy bilious-looking matter followed, but no more calculi. The calculi had evidently become dissolved. The patient was left with directions to repeat the use of the oil a few times, at intervals of two or three weeks, and after this as might be indicated by the recurrence of symptoms threatening the return of the paroxysms. I saw the patient five months after my first visit. While there were indications of organic disease of the liver, no more calculi had been passed, and the paroxysms had ceased to return.

Mrs. W. F—, of Ernestown, presented a case very similar to that of C—. She had for some years suffered from fits of intense pain, generally coming on after a hearty meal. She was directed to take full doses of the oil for two consecutive days. She passed about two hundred calculi, varying in size from a grain of wheat to a filbert. The periodic attacks of pain ceased with the removal of the gall-stones.

Gabriel B— and Clinton F—, both of this township, each presented a case of hepatic disease, characterised by obstruction to the flow of bile, accompanied by severe pain. The oil was administered with the effect of removing softened calculi of considerable size, but in smaller numbers than in the preceding cases, the general symptoms being relieved. A number of other cases might be referred to, in all of which the power of the oil to soften and facilitate the expulsion of biliary calculi was shown to be prompt and unequivocal.

The material point which may be deduced from these cases is that olive oil, administered in repeated large doses, seems to have an unquestionable power of so softening and partially dissolving biliary concretions as to render their expulsion comparatively easy.

Another fact I have noticed is, that although the administration of the oil at intervals of a few weeks or months does prevent the re-formation of the concretion for the time, yet the resort to the oil alone does not alter the causes or diathesis upon which the formation of these bodies depends.

A FIFTH CASE OF EXTRA-UTERINE PREGNANCY TREATED BY ABDOMINAL SECTION.

By LAWSON TAIT, F.R.C.S.

E. A—, aged forty, admitted to the hospital early in June. She had been married nineteen years, had five children, the youngest of whom was nine years old. She had been a strong, healthy woman until last November, when she missed a period, and very soon after had an attack of violent pelvic pain, accompanied by great prostration and sickness. She continued in bad health till March last, when she was examined by Dr. Wigglesworth of Liverpool, and declared to be pregnant. She applied to the Birmingham Hospital for Women at the end of May, when the diagnosis of extra-uterine pregnancy was made by Dr. Hickinbotham and myself in consultation, and she was admitted.

On June 30th I opened the abdomen, and found the pregnancy to be seated in the right broad ligament, the Fallopian tube having ruptured at its lower aspect and the ovum escaped into the tissue between the folds, as has been the case in all the instances I have operated upon. I made an opening at the upper and anterior part of the cyst, removed the child, which we had previously been quite certain was dead, cleaned out the cavity, stitched the margin of the

wound in the cyst to the wound in the abdominal wall, and left in a wide glass drainage-tube. All the details were precisely those described at length in the record of my previous cases published by the Royal Medico-Chirurgical Society.

During the next three weeks the placenta came away in pieces, the cavity gradually closed, and she left the hospital on August 16th quite recovered, and is now in perfect health.

Birmingham, Sept. 14th, 1880.

INFANTILE DIARRHŒA IN NEW ZEALAND.

By LEIGHTON KESTIVEN, M.R.C.S. ENG.

THIS affection, which is principally coetaneous with summer heat in this colony, and from its prevalence becomes epidemic in its character, is of a far more serious nature than the ordinary summer diarrhœa met with among infants in the home country, and from which indeed it is almost a distinct affection. The disease here has the same commencement as the ordinary form, consisting of loose slimy motions and cramping pains in the abdomen; but in the severe form which it takes here—I have most frequently noticed as a premonitory symptom a discharge from the rectum (*previous to any loose stools*), small in quantity, and occurring only once, of thick lymph immediately before the diarrhœa has set in. Though I am unable to give any explanation of this, I have invariably noticed that the disease has then assumed the very worst form, and the motions have immediately become watery and mucous. At this stage constant sickness and loss of appetite supervene, rendering the administration of nourishment or medicine a task of great difficulty, and extreme emaciation sets in; the weakly succumbing here, and the stronger ones later on, of exhaustion, or dragging through a long and tedious recovery.

In the severer cases, however, the watery stools are succeeded after two or three days by intense tenesmus and tormina, accompanied by inability to retain the motions, and the complaint then assumes the character of acute dysentery. The stools become bloody, often consisting of little else than bright red blood and slimy shreds, unaccompanied, however, by any purulent matter. The constitutional disturbance is very great; tongue furred; pulse rapid and small, temperature as high as 100° or 101° F., and the respiration accelerated. No delirium. The little patient remains in this state for two or three days, or even less, when exhaustion sets in very suddenly; the temperature drops from 101° to 96° or 97°, and death occurs within twenty-four to forty-eight hours after.

The mortality in both forms which I have described is very great at all ages up to five or six years, after which it diminishes. This, I believe, is the case in all the Australian colonies; where this complaint takes the same form. Why it should assume such a severe character in these colonies it is difficult to give any accurate explanation; but from personal experience and a careful comparison of statistics I am inclined to assert that it is the impurity of the drinking water that is the chief factor in the disease, and that the warmth of our climate, which renders children such ready subjects to the disease, causes its extreme fatality. Thus, in Wellington, where the climate—though warm—has been less so than in other towns in New Zealand, the infant mortality (according to the Registrar-General's returns) has been greater by far from diarrhœa than in any other town in New Zealand, microscopic and analytical examination of its drinking water showing it to be swarming with animal and vegetable life, and loaded with decomposed organic matter in solution; whilst the water in other towns in the colony has been of a far better quality for drinking purposes. Children, too, in New Zealand are greatly infested with intestinal worms; which, though not the necessary factors of this disease, must tend greatly to aggravate the mischief and retard a cure.

Treatment, however, is, I regret to say, of little efficacy, and the only drugs which I have found of the least specific curative use have been the extract of Indian bael in combination with creasote, opium, and bismuth; and the Maori's favourite drug "koromiko," a native indigenous shrub, generally used as an infusion or spirituous decoction. Sul-

phuric acid I have invariably found to greatly aggravate the diarrhœa, whilst I have fancied I have seen in one or two cases a decided improvement under small doses of carbonate of soda and borax. A mixture of minute doses of castor oil I have heard greatly extolled, but I have found it very mischievous even when combined with opium and cardamoms. I have, however, been in the habit of administering a full dose of the oil previous to treatment with other drugs, and I believe it to be necessary or useful in removing any source of irritation to the bowel.

Nourishment, to be of any service, must be little and often, on account of the want of appetite and delicacy of stomach, but it is necessary to exercise very great care in this matter, as the irritability of the intestines is so great. Milk, portwine, and the juice from half-cooked mutton are utilised most easily, whilst strong chicken jelly is a capital change of diet. Brandy should be administered plentifully from the first.

The pathology of these cases has been most indistinct in the few cases I have had the opportunity of making an examination, consisting in patches of more or less extreme congestion here and there in the mucous coat of the intestines throughout their entire length, amounting in the lower bowel to solution of surface continuity, but without any discernible deposit of pus being elicited even by microscopic examination.

Two or three points in this account seem to me worth drawing attention to, as I have neither met with them myself nor read of them, as occurring with this disease, outside of these colonies—viz., the premonitory lymphous discharge, the rapid fatality of the severer cases, the early assumption of the dysenteric character and sudden termination, and the absence of ulceration (true) or sloughing of the bowel which occurs in dysentery.

Climate, of course, modifies many diseases; but the difference between the home climate and ours does not seem to me to be enough to account for the extreme severity and variation of the disease as it occurs here.

Wellington, N. Zealand.

CASE OF CHRONIC GASTRIC ULCER, WITH TOTAL ABSENCE OF SYMPTOMS: PERFORATION; PERITONITIS; DEATH.

By W. G. CRESWELL, L.R.C.P., L.R.C.S. EDIN.,
MEDICAL OFFICER OF HEALTH, SALTLEY.

THE following notes from my case-book will, I think, be of interest, inasmuch as they point out the insidiousness of the above disease even more fully than does Mr. Lacey's case, reported in the issue of THE LANCET of April 24th last:—

E. C—, aged twenty-one, a factory girl, who had *never even complained of any morbid symptoms* since childhood, had on the afternoon of Dec. 27th, 1879, a sudden attack of "shivering," but was otherwise apparently all right. At tea-time, while stooping to toast some bread, she felt "something wrong" in the chest and epigastrium, and immediately went upstairs and to bed, where she vomited at frequent intervals a brownish fluid, and also everything she took. At the same time she complained of great epigastric and abdominal pain. These symptoms continued all night, and at 11 A.M. the next day she died in her brother's arms as he was carrying her by her own desire into the next room. I saw her at 12.30. She was then quite stiff, lying on her back with both hands clenched, and the right arm bent at right angles at the elbow, the hand pointing upwards. The legs were extended.

By the coroner's order I made a post-mortem examination on the afternoon of Dec. 31st, about seventy-eight hours after death. The body was of good physique and well-nourished; a little post-mortem discoloration present. On opening the abdomen, it was found to be full of a muddy milky fluid. At the upper part of the cavity both the peritoneum and the intestines were much congested, and slight adhesions were present in many places. There was but little gas or smell. The stomach was empty, and showed on the posterior surface, near the pylorus, a clean-edged round aperture, the eighth of an inch across. On examination of the inner wall, the ulcer was seen to be funnel-shaped and surrounded by considerable thickening. Other

parts of the gastric wall showed patches of congestion and erosion, but most probably these were not present during life. The heart was of large size, but healthy. The right auricle and large veins were distended with firmly-clotted blood, and this hyperinotic condition was more or less present generally. The hymen was intact, and the ovaries much congested, a menstrual period having been completed only two days before death.

After the most careful questioning, I could gather no account of any gastric symptoms, poor living, intemperance, anæmia, abnormal menstruation, or mental anxiety. The absence of hæmatemesis, or vomiting, was the more remarkable considering the anatomical position of the ulcer, which again, though perforating, was yet attended by the funnel-shaped thickening of a chronic ulcer. The other points of interest were the large size of the opening, and the attack of shivering coming on before the advent of pain. There was also marked absence of hour-glass contraction.

In the presence, however, of all these uncommon conditions, it will be noted that the patient was of the usual sex and age, and that the ulcer was in the usual anatomical site. Saltley.

Nulla enim est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

SAMARITAN FREE HOSPITAL.

CASES OF RUPTURED PERINEUM.

(Under the care of Dr. GRANVILLE BANTOCK.)

CASE 1. *Complete rupture of perineum, with an inch of recto-vaginal septum; immediate operation; imperfect result; operation; cure.*—Mrs. B—, aged twenty-four, was admitted June 15th, 1878. The perineum was ruptured through the sphincter, with about an inch of the septum, in the second confinement, eleven weeks before admission. Some stitches were applied at the time of the accident, but the result was a very thin membranous perineum, and a recto-vaginal fistula large enough to admit a No. 12 catheter, through which flatus and fluid fæces passed into the vagina.

On June 17th the imperfect perineum was cut through, the edges of the fistula were pared, and a triangle of raw surface was formed at each side, the two meeting by their bases in the middle line of the septum; seven sutures of fine silkworm gut were used to bring the rectal edges of mucous membrane together, the ends being cut off short, and four deep sutures were employed for the perineum proper.

No opium was given. The highest temperature, 99.4°, was recorded in the evening after the operation. The bowels were moved on the fifth day by a pill containing colocynth and hyoscyamus. On the seventh day the perineal sutures were removed, and the patient went home on the seventeenth day.

CASE 2. *Complete rupture of perineum, with over half an inch of the septum; operation; cure.*—Mrs. K—, aged thirty-one, admitted Feb. 25th, 1879. The perineum was ruptured in the first confinement, six months before admission, after a labour lasting nineteen hours and terminated by forceps. Nothing was done to the perineum. There was no control whatever over the semi-fluid fæces or flatus.

On February 26th the usual operation was performed. Seven sutures of silkworm gut were inserted in the recto-vaginal septum and three deep perineal sutures.

No opium was given after operation. The bowels were opened on the fifth day by pills of colocynth and hyoscyamus given at intervals of four hours. The perineal sutures were removed on the seventh day, and the patient went home on the seventeenth day.

CASE 3. *Complete rupture of the perineum to the sphincter; retroversion of the uterus with rectocele and cystocele; operation; cure.*—Mrs. E—, aged forty, admitted June 24th, 1879. Four children; last in September, 1875. Treated for prolapsus by a variety of pessaries until she came under

the notice of Dr. Wynn Williams (in the out-patient department), who admitted her for operation.

On June 27th, in addition to the usual double triangle, the denudation was extended about an inch up the septum, ending in a point. The vaginal mucous membranes were brought together by seven fine sutures, and the perineum was secured by five deep sutures.

No opium was given after operation. The bowels were moved on the fifth day, and on the tenth day the perineal sutures were removed. The healing process was so complete that the line of union could not be distinguished.

This patient was not able to leave the hospital till the twenty-third day in consequence of a slight attack of cystitis.

At a later period, some weeks after, Dr. Williams relieved her from the symptoms due to the retroversion by applying a Hodge's pessary.

CASE 4. *Complete rupture of perineum, ten years ago, with part of the septum; immediate operation; failure from excessive constipation; operation six months after; failure; operation; cure.*—Mrs. S—, aged thirty-three, admitted December 10th, 1879. The perineum was torn completely, with part of septum, in the first confinement, after a labour of over twenty-four hours, terminated by forceps. Sutures were at once applied, and the bowels were kept confined for seven days. At that time the perineum appeared sound, but the evacuation was so solid that the whole gave way. After this she had no control over semi-fluid evacuations. Six months later she was operated on, but without any benefit.

On December 13th the usual operation was done. Four sutures in the rectum and five deep perineal sutures were inserted.

No opium was given until the next day, when two doses of fifteen and twenty drops of the tincture of opium were given respectively for pain preceding the menses, which appeared on the third day.

On the fifth day the bowels were freely opened after three pills of colocynth and hyoscyamus, given at intervals of four hours. The perineum was quite sound and absolutely free from irritation. On the ninth day the perineal sutures were removed, and the patient went home on the eighteenth day.

CASE 5. *Complete rupture of perineum and through the sphincter five years ago; operation; cure.*—Mrs. R—, aged thirty-seven, admitted March 11th, 1880. Five years before she was delivered of her sixth child by forceps, and felt unusually sore for some time afterwards. On getting about she found she had lost control over the bowel. Her condition in this respect was confirmed by the difficulty the nurse experienced in giving her an enema. Two years before admission she entered one of the general hospitals, where she was told she was too weak to undergo operation.

On March 15th, at 10 A.M., the usual operation was performed. Six sutures were inserted in the rectum, four in the perineum, and an uninterrupted horsehair suture was inserted in the vagina.

As the patient complained of some pain, twenty drops of tincture of opium were given at 2 P.M., also at 9 P.M., and again at 9 P.M. next day. On the fourth day the bowels were opened by a dose of Janos water, followed by a small enema. On the seventh day the perineal sutures were removed: the wound was quite healed, but the two stitches next the anus had cut the skin a little. The same night the menses appeared, preceded by a great deal of pain. She went to a convalescent home on the fourteenth day.

CASE 6. *Abscess in the recto-vaginal septum, resulting in recto-vaginal fistula and labial sinuses; fistula and sinuses freely laid open, the former by cutting through the perineum; operation subsequently; cure.*—M. D—, aged twenty-nine, single, was sent to hospital by Dr. Edis, and admitted on Jan. 12th, 1880. For several years she had complained of pain on sitting down, but was not aware of anything serious till October last, when she had an abscess, with the usual symptoms, which first broke into the rectum and afterwards at the vulvar orifice. From that time she suffered from repeated "gatherings." On examination an opening was found at the lower end of the right labium, from which thin pus exuded on pressure. A probe passed into it went backwards and inwards towards the middle line, and its point could be felt in the rectum within the sphincter. Another small opening at the bottom of the fossa navicularis led straight through into the rectum behind the sphincter.

On Jan. 19th the fistula was laid open by cutting through the perineum, the sinus from the right labium was freely incised, and a small abscess cavity on the left side, communicating with the fistula, was also laid open. The parts thus exposed were stuffed with lint saturated with equal parts of glycerine and sulphurous acid; after this with a watery solution of the same acid gradually reduced in strength to 1 in 20. After several weeks the patient was sent out, and was readmitted on May 11th with the parts soundly healed, but with a hæmorrhoidal condition of the mucous membrane around the rectal opening.

On May 12th, after due denudation, the rectum was restored by means of six fine sutures, whose ends were cut off short, as usual, and the perineum was brought together with five deep sutures.

No opium was required or given. The bowels were opened by three pills (given as above) on the fifth day; three of the perineal sutures were removed on the ninth day; on the eleventh the menses appeared; the remaining two sutures were removed on the fourteenth day, and the patient went to the seaside on the nineteenth, with the perineum quite sound.

CASE 7. Complete rupture of perineum with part of septum five months ago; operation after four months; failure; operation; cure.—A. W—, aged nineteen, single, a very stout young girl, sent by Dr. Dow of Pembroke-square, was admitted on June 15th, 1880. She was delivered by forceps in Jan. 7th last, and felt very sore afterwards. Nothing was done to the perineum, and she soon found that she had no control over the bowel, and had semi-fluid evacuations. She was operated on a month before at one of the general hospitals, when the quill suture was used. The result was a failure.

On June 16th the usual operation was done; six sutures were inserted in the rectum, and four deep sutures in the perineum. As there was rather more venous oozing from the edge of the vaginal mucous membrane in middle line, a small piece of sponge was left in the vagina just within for a few hours.

No opium was required. The bowels were opened by pills and Hunyadi on the sixth day, on which day, also, the menses came on. For the next three days menstruation was excessive, and some ergot had to be given. On the tenth day sutures were removed, with all healed, and on the nineteenth day she left the hospital.

Remarks by Dr. BANTOCK.—It will be seen that in only one case (No. 5) was any opium required, and then it was doubtful whether the pain was really at the site of the operation. The patient was a weak nervous woman, and appeared to bear pain very badly. The absence of pain after the method adopted in these cases contrasts strongly with what is observed after the old method of using the quill suture, as in Case 7. The patient voluntarily made the contrast, and said that she had suffered very severely for three days in her previous operation. It will be seen also that opium was not given for the purpose of keeping the bowels quiet and constipated. The disastrous effect of such a practice is well exemplified in Case 4. The quietude of the bowels for several days is ensured by their pre-evacuation previous to operation, and by the light diet which suffices for the first three or four days. On the fourth day I usually begin to administer some mild aperient, and for this purpose a pill, consisting of one grain each of the compound colocynth extract and hyoscyamus, given every four hours till the bowels act, is to be preferred. Sometimes the nurse is instructed to examine the rectum, and if hard fæces be found, to throw in from a quarter to half a pint of soapy water. This small quantity excites very little irritation, and may be retained for several hours, during which time it slowly does its work by softening what may be in the rectum. It is better that the evacuation should be slightly formed. Liquid matter is apt to insinuate itself into, and so irritate, the wound. Thus while measures are taken to avoid constipation, and to procure an early evacuation, it is undesirable that the bowels should be moved before forty-eight hours have elapsed. I now always cut off the rectal sutures close to the knot, and they give no trouble as a rule. Twice where the ends have been left about a quarter of an inch long it has been necessary to remove some of them a few weeks after. But with the ends cut off short the knot becomes embedded in the soft tissues, and the suture ultimately disappears by absorption. It is of great importance to get the bowels moved before the sutures are removed, for the sutures strengthen the perineum and anal opening. As the silkworm gut pro-

duces absolutely no irritation, provided the sutures be not drawn too tightly, this result is easily obtained. In no case has any alcoholic stimulant been given, nor has any antiseptic been employed. The raw surfaces should, however, be made very clean, and all bleeding should be stopped before the perineal sutures are drawn together. As a rule, there is very little bleeding, as scissors are chiefly used, and what little bleeding there may be is usually to be controlled by hæmostatic forceps.

So far I have not had a failure, and I attribute this to the simple suture and the silkworm gut. I have also the satisfaction of knowing that others who have adopted my method have been equally successful—notably Mr. Square, jun., of Plymouth, who tells me that he has now no hesitation in attempting the severest case, and with confident anticipation of success.

MANCHESTER ROYAL INFIRMARY.

APPARENT TYPHOID FEVER; CEREBRAL HÆMORRHAGE; DEATH.

FOR the following notes we are indebted to Mr. J. Hodgson, M.R.C.S., house-physician.

J. F. T—, aged forty-four, married, was admitted on June 14th, 1880. He stated that his previous health had been good, and that the present illness began with a fit of shivering one week before admission. Beyond this no history was obtained, owing to the patient's mental condition.

The following signs and symptoms were noticed: A husky voice, very slight cough, and a small amount of rusty sputum; fetid breath, a dry tongue, thickly coated with brown fur, except at the tip and edges, which were red; harsh breathing generally, slight relative dullness at the base of the right lung, accompanied by a few bubbling râles in that region, but no true crepitation or tubular breathing. There was no rash, no tumidity of the abdomen, but a little tenderness on pressure in the right iliac region. There was considerable enlargement of the spleen, as well as slight enlargement of the liver. The pulse was regular, 92, the heart-sounds were normal, the temperature 103° 2' F., and the urine contained abundant albumen. Laryngoscopic examination showed the usual signs of catarrhal laryngitis. A milk diet and small doses of quinine were prescribed.

The next morning there was a slight remission in the temperature, but with this exception during the day the temperature continued between 102° and 103°; the physical signs underwent no alteration, the patient was frequently delirious and suffered from delusions of a religious character.

On the third day after admission, between four and five in the morning, the patient complained that he had lost the use of his right arm, and before long hemiplegia was well developed, the right side of the face and the right arm and leg being affected. Speech was not lost. Ophthalmoscopic examination showed that the discs were normal.

At 1.30 P.M., the bowels not having been moved since admission, a simple enema was given, which was followed by "pea-soup" evacuations. At five o'clock the abdomen was distinctly distended and tympanitic, the skin was exceedingly hot (temperature in the axilla 107° F.), and the patient became comatose, and died.

Necropsy revealed a recent hæmorrhage, occupying a large part of the left cerebral hemisphere. The blood, which had evidently been primarily poured out into the substance of the brain, had found its way into the lateral ventricle of the left side. The right ventricle contained a clot of blood, much less than that in the left. The basal arteries seemed healthy. The lungs were congested and œdematous at the bases, but showed no signs of hepatisation. The valves of the heart were healthy; there were no signs of endocarditis or pericarditis. In the lower part of the ileum a few congested spots existed, about a quarter of an inch in diameter, these were in some instances raised and hard to the feel. One or two of Peyer's patches near the ileo-cæcal valve were congested. The large intestine presented in its whole length numerous congested and raised spots, similar to those seen in the ileum; many of these were distinctly ulcerated. The spleen was considerably enlarged, weighing twenty-one ounces, and contained a large hæmorrhagic infarct, surrounded by several small ones. Abundant "pea-soup" fæces made their escape from the anus as the body was being placed upon the table.

PROFUSE INTRA-CRANIAL HÆMORRHAGE; INTENSE HEAD-ACHE; VOMITING; DELIRIUM; ABSENCE OF HEMIPLEGIA; COMA; GLYCOSURIA; DEATH.

H. N.—, aged thirty-eight, married, was admitted on May 22nd, 1880, at 11.30 P.M. He was very pale, his skin was cold and moist, and his pulse was weak; he was delirious, and complained of intense pain in his head. No trace of hemiplegia could be discovered, the patient walking into the ward with the assistance of his friends. The pupils were normal. He was put to bed, and an ice-bag was applied to his head. Shortly afterwards there was some vomiting.

At half-past one the next morning he became very violent and noisy; at five o'clock he was comatose, and at seven he was dead. Some urine was drawn off by the catheter, and found to contain sugar. It was ascertained from his friends that he appeared to be in perfect health up to the day of his admission; that he had spent that day at some pleasure-gardens, and had had no alcohol beyond three glasses of beer; that he was about to start for home when he suddenly complained of severe pain in his head, and shortly afterwards became temporarily unconscious on his way to the infirmary.

At the necropsy a dark clot was found, filling the lateral, third, and fourth ventricles of the brain; blood was effused over the base of the brain, and had extended upwards over the surface of the hemispheres, filling the sulci. The large ganglia and other important structures at the base of the brain were uninjured. No ruptured vessel or aneurism was discovered. The lungs were emphysematous. The heart, liver, spleen, kidneys, and other organs were healthy. There were no marks of external violence.

Reviews and Notices of Books.

The Utricular Glands of the Uterus, &c. By Prof. ERCOLANI. Translated under the direction of H. O. Marcy, A.M., M.D. Trübner and Co.

THE work of Professor Ercolani has been long known in its main feature to those who have followed the researches which have been recently made into the structure of the placenta; for although the title of the work would scarcely lead one to expect it, yet the main object of the author is to prove a view which he has been led to adopt of the structure and function of the placenta, while the description of the utricular glands of the uterus forms but a part, though a very necessary part, of the evidence which the author produces in support of his theory. This theory is as follows:—"There is produced in the pregnant uterus of mammals, including the human species, a glandular organ of new formation. This organ constitutes one of the two fundamental portions of the placenta, that is to say, the maternal portion, with which the fœtus is brought into intimate contact by the villi of the chorion, which composes the other portion of it, or the fœtal part. The villi of this latter part of the placenta penetrate always and obviously into the glandular organ or maternal part, in order to absorb the fluid which is there secreted, and thus to furnish the fœtus with the materials necessary for its nutrition."

With a view to establish this theory the author gives an account of "the utricular glands in mammalia in the gravid and non-gravid animal," their development and function; he points out their increase of size in the gravid state, and adopts the opinion of Eschricht that these glands, together with the simple follicles, "elaborate, during gestation, a fluid destined to furnish some elements for the nutrition of the fœtus, particularly when the organs which are charged with that office, or the villi of the chorion, are not fully developed." The human decidua, it is said, "may be considered as a product of exudation, due for the most part to the utricular glands, and the numerous openings which perforate it obliquely precisely indicate the mouths of these glands, which remain open in the decidua for the con-

tinual passage of the materials elaborated by the glands." In accordance with this view the author explains the formation of the decidua reflexa. He states: "Now if, according to the preceding observations, the uterine or true decidua is only a product of exudation, due in great measure to the secretion of the uterine glands and to the transudation of organisable fluids from the internal surface of the uterus, it becomes easy to comprehend the formation of the reflected decidua. While the whole internal surface of the uterus is covered with the uterine decidua, the ovum when reaching the uterus is also covered with a similar layer, formed by the same materials, which further serve to fix it at one point of the uterus. At this point the uterine and the reflected decidua are soon mingled together, precisely as will take place later, when the ovum, increasing in size, forces the reflected decidua which surrounds it against the uterine decidua, so that the two decidua blend into one single membrane." The serotina again is described as follows:—"This membrane, produced by the proliferation of the cells of the superficial or submucous connective tissue of the uterus, is the stroma whence originates the glandular organ which supports and envelops the villi of the fœtal placenta in all their subdivisions." The author never tires of emphasising his view that the maternal part of the placenta is a new formation, owing "its origin in the human species to the new formation of special cells, which in the human species has received the name of decidua serotina." It has nothing to do with the glandular structure of the unimpregnated uterus. Indeed, Ercolani maintains that a "primordial destruction, more or less marked, of the uterine mucous membrane, is indispensable for the beginning and completion of the new formative process, from which, in all cases, results the development of the maternal portion of the placenta." Finally, it is held that the nutrition of the fœtus is not maintained by osmotic processes between the blood of the mother and that of the fœtus, but by absorption by the epithelium of the chorion villi of a fluid secreted by the cells of the serotina, which cover the chorion villi, and this is the case, however intimate the union may be between the fœtal and maternal parts of the placenta. It should be stated, further, that the author accepts the view that the placenta contains large sinuses possessing thin walls, and that these thin walls cover the fœtal villi in all their parts, and are closely united to them; that the blood of the mother is passed into these sinuses in its course from the arteries to the veins.

It would be impossible to enter here into the details of the descriptions of the placenta of various animals and of the human species found in this work. We can only notice some of the main conclusions arrived at by the author. With reference to the manner of nutrition of the fœtus by absorption of secreted material rather than by osmosis, our knowledge does not warrant any positive statement. The question is an extremely difficult one. There is great probability that such is the mode before the formation of the placenta; but the evidence brought forward in the work before us fails to prove such to be the case after that period.

The term "mucous membrane" is used in a peculiar sense by the author, for he says, "In woman . . . the simple epithelial layer, which by itself represents all the mucous membranes of the uterus, . . ." Now this use of the term is one not generally accepted, and is, moreover, one which gives to the views promulgated a much more startling character than they really deserve, but for positive statements made by him (and quoted above) with regard to the nature of the decidua and serotina. In the destructive process preceding the process of formation of the placenta it turns out that in the human female it is only the epithelium which is destroyed, and the real question at issue between him

and other observers becomes one of interpretation. With regard to the nature of the decidua reflexa, it has been incontrovertibly proved that it is an upgrowth of the decidua vera around the ovum at the point where the descent of the ovum has been arrested. It has been observed in process of formation, and it presents a structure precisely similar to the vera, including the presence of utricular glands. The serotina again, instead of being a new formation, has been shown to be but the deeper layer of the decidua vera at the insertion of the placenta, while the vera when examined soon after conception, presents all the characters of the mucous membrane of the uterus. The changes in these structures have been traced from month to month, both those in the cellular elements and in the glands. The nature and formation of the peculiar cells of the decidua is a subject upon which we still require further knowledge, and is one upon which there is ground for difference of opinion; but the evidence as to the development of the decidua vera, decidua reflexa, and decidua serotina from the mucosa uteri, remains untouched. The work before us contains the results of great research both in the study and in the dissecting-room. It gives a mass of information with respect to the views which have been hitherto held with regard to the uterine glands and placenta. It moreover brings prominently forward a subject which deserves more attention than it has hitherto received—that is, the part played by the glands of the uterus during pregnancy.

The translation has been made by Messrs. Smead and Jacobs, under the supervision of Dr. Marcy, and is on the whole well done. Some passages are, however, obscure in their meaning; whether this be the fault of the translator or of the author, we cannot say. The work is one not likely to have a large sale, and the publishers for this reason, amongst others, deserve the highest praise for their enterprising spirit.

The Diagnosis of Diseases of the Spinal Cord. An Address delivered to the Medical Society of Wolverhampton, Oct. 9th, 1879. By W. R. GOWERS, M.D., F.R.C.P. London: J. & A. Churchill. 1880.

THE remarkable advances made in the study of nervous disease and nerve-physiology is well illustrated in the history of our knowledge concerning the spinal cord. It would have been impossible ten years ago for so thorough a survey as the present lecture to have been penned; for there is hardly a page that does not contain some new fact, throwing light upon the function of the cord, and aiding in the exacter diagnosis of its morbid condition. The glory of Duchenne was to have definitely separated locomotor ataxy from the heterogeneous group of the paraplegiæ; but it has been left for his posterity to further analyse this group, and complete the differentiation which he set afoot. Nor must it be imagined that there are not obscurities still to be cleared up; and time may show that in some of their interpretations of phenomena the present generation have failed to grasp the whole truth. They have, however, added so much to the store of knowledge that, as compared with the preceding generation, we walk in the light, where they groped in darkness.

Dr. Gowers, so far as the limits of his book allow, deals with the several points worth knowing in spinal diagnosis. After some remarks upon the medical anatomy of the spinal cord, he discusses its physiology in relation to the symptoms of its diseases. It is here—and especially in the department of reflex actions—that most advances have been made. The integrity of the spinal cord can be fairly well deduced from the perfection with which the reflex actions are carried on—under due allowance for age and idiosyncrasy. The interesting fact that the superficial reflexes are lessened or abolished on the paralysed side in cerebral hemiplegia is at first sight

difficult of explanation, especially as the “deep” reflexes (tendon-reflex) are increased in such conditions. Dr. Gowers points out the probable explanation. In the frog the superficial reflexes are controlled by a centre in the optic lobes; in man by one in the corpora quadrigemina. Now it is most likely that this controlling centre in man is itself kept in check by the higher motor centres. If their influence be removed by a lesion in the hemisphere, the controlling centre has full play and the reflex action is restrained. On the other hand, if there be a lesion in the cord itself the reflex action is increased. Of course we have long been familiar with the fact of the control exerted by cerebral centres over the spinal; but the explanation of the difference between cerebral and spinal lesions in their effect on the spinal reflexes has not been so clearly stated. After this, Dr. Gowers treats at some length upon the subject of “tendon-reflexes”; although he points out that the term “tendon” is too limited, and prefers to style them “knee-reflex” and “ankle-reflex.” This is a very interesting inquiry, which has already borne good fruit in giving early indications of the presence of spinal cord disease. There seems no reason why other “deep reflexes” than those already discovered may not be added to the list; but those at present in common use are amply sufficient for practical purposes. Inco-ordination is attributed to impairment of reflex action. Other points in spinal physiology are necessarily dealt with, and in the next section the author proceeds to deal with the Anatomical Diagnosis of lesions. He gives an ingenious diagram and table showing the approximate relation to the spinal nerves of the various motor, sensory, and reflex functions of the spinal cord; and it is remarkable with what accuracy it is now possible to determine the exact level of a lesion. Then comes a section on Pathological Diagnosis, and the features pointing to the probable nature of the morbid change are passed in review. Lastly, some cases are given illustrative of the methods of diagnosis expounded in the book.

Dr. Gowers has throughout the work aimed at simplifying the nomenclature of the spinal cord. Thus, in speaking of its anatomy, he, to our thinking, wisely discards the phrases “columns of Goll,” “of Türck,” “of Burdach,” which only land the reader in hopeless confusion; and prefers to speak of these regions as the “postero-median column,” direct “pyramidal tract,” and “root-zone.” He is not quite so happy in substituting the term “cornual myelitis” for “anterior polio-myelitis;” for the latter, in spite of its uncouthness, is etymologically more correct and free from the charge of hybridity. Medical terminology is, however, so full of hybrid phrases, that this slight criticism may be thought too exacting.

In conclusion, we are thankful to the Wolverhampton Medical Society, at whose invitation Dr. Gowers delivered this lecture, for it has resulted in the production of a handbook which is a credit to our literature.

Archives de Neurologie. No. I. Paris: 1880.

It is singular that France, which has produced so many writers in the field of neuro-pathology and physiology, should be almost the last country to have started a journal specially devoted to this subject. The gap is now filled, and the first number of a new quarterly journal devoted to these topics has just appeared, under the direction of M. Charcot. The editor is M. Bourneville, and the journal is published at the office of the paper which that gentleman also edits—*Le Progrès Médical*. An introduction by M. Charcot explains the reasons for its publication, and indicates the field proposed to be traversed in its pages. Whilst admitting the danger of the present age to multiply specialities, he points out that the wide relations of the nervous system to all parts of the organism render the institution of

a journal specially devoted to its consideration far less limited in scope than appears at first sight. The *Archives* will deal principally with nosography and records of clinical observation, but will also embrace normal and pathological anatomy and physiology, experimental and therapeutical researches. This first number contains articles bearing upon almost every one of these departments. Thus, under the head of anatomy we have a short paper by Debove and Gombault upon the decussation of sensory fibres in the medulla. The point was settled by the examination of the medulla in a case of lateral amyotrophic sclerosis; and they clearly show that after decussation the sensory filaments mingle intimately with the motor fibres of the pyramids. A short note by M. Debove on the preparation of the spinal cord for microscopical examination follows. He keeps the cord for three weeks or longer in a 4 per cent. solution of bichromate of ammonia, then for three days in a carbolised gum solution, then for three days in alcohol. The sections made and the gum washed out, they are left for twenty-four hours in a saturated solution of picric acid, after which they may be readily stained with carmine. This process has yielded him better results than any other. Under the heading of Experimental Pathological Anatomy there is the first instalment of an investigation by M. Gombault upon the nerve-changes in subacute and parenchymatous neuritis. He has studied these lesions in guinea-pigs slowly poisoned by lead, and describes and figures degeneration and disappearance of the myelin limited to different segments of the nerve-fibre in this condition; and he further illustrates the lesion by changes similarly observed in muscular atrophy and traumatic neuritis in man. Under Pathology there is an article by M. Debove and M. Boudet de Paris upon the Motor Inco-ordination of Ataxies, where they attempt to prove, chiefly by means of the use of the "myophone," that inco-ordination is due to unequal tonicities of the muscles, and that its effects are diminished by their maximum contraction. Under Mental Medicine there is a lengthy and learned article by M. Magnan demonstrating the frequent co-existence of different kinds of delirium in the same insane subject; and the first part of an interesting contribution to the clinical and pathological study of Idiocy by M. Bourneville. The section of Therapeutics is represented by the record of two cases of hemiplegia, in which motor power and sensibility were restored by the use of magnets. This, again, is by M. Debove. A review of present knowledge upon Cephalic Thermometry by M. Boyer follows; and the closing pages of the journal are devoted to abstracts of recent published work in various departments and to a few reviews of books. Altogether the number is full of interesting and readable matter, and if the journal fulfil the promise of its first issue in subsequent numbers, it will, no doubt, be widely read. The second issue is to appear on October 1st, and, like our own publication in the same field, *Brain*, it is to be published quarterly.

New Inventions.

HALL'S PATENT VENTILATOR AND CHIMNEY-COWL.

THE accompanying engravings represent one of various types of the improved ventilator invented by Alfred Hall, M.D., F.R.C.P. London. Its main feature consists in an aggregation of four, six, or any other binary number of tubes or orifices surmounting the soil-pipe or other conduit from which foul air or fetid smells are emitted, and a glance at our illustrations shows that the object aimed at is attained without the use of any mechanical contrivance, or of any very intricate construction like those that form perfect labyrinths in some other ventilating arrangements.

Fig. 1 is a front view of the ventilator, representing the two orifices, B' B", that adjoin one another; Fig. 2 is a longitudinal section, and Fig. 3 a horizontal section taken through the line α - β , Figs. 1 and 2. A is the soil-pipe or

other conduit to be ventilated or disinfected; it is in the present instance surmounted by a system of six orifices, B B, closed up at the top by the helmet, c, and half trumpet-shaped at the bottom, as shown in section at b, Fig. 2. The current of air passes through the orifices B B, B' B', B" B", opposite one another, and a continuous exhaustion of the foul air or noxious vapours is secured by this means.

We have remarked that our illustrations represent but one out of a number of types of the same ventilator, which may equally well be used as a chimney-cowl. Another type is that of an ascending soil-pipe closed up at the top and surmounted simply by a cross of four short horizontal tubes, through which the suction of the fetid air takes place. This ventilator may be made of tinned iron or zinc plate, as well as of copper or terra-cotta. There being no mechanical contrivance or appliance of any kind connected with it, it is not likely to ever get out of order; and, if made of copper, it is practically indestructible.

Analytical Records.

DUROLEUM (HARD OIL).

(FERRIS, BOORNE, & CO., BRISTOL.)

TASTELESS, odourless, and unalterable preparations made from petroleum are rapidly superseding lard in pharmacy. Messrs. Ferris's new ointment-basis is excellent, and, though similar to several already in use, is firmer, which in hot weather, and especially in hot countries, is an advantage. We have received more than a dozen different samples of ointment made with duroleum, all excellent in quality, and certain to keep. The price is exactly the same as for ordinary P. B. ointment.

BARON LIEBIG'S LEGUMINOUS COCOA POWDER.

(P. STEIN, 7, IDOL-LANE.)

In this preparation of cocoa a portion of the fat has been removed and a portion of legumin added. Thus a highly nitrogenous food is obtained, rich in actual proteic or flesh-forming material. Chocolate prepared from this powder is excellent in flavour, and free from the somewhat unpleasant taste often observed in leguminous preparations. We think it a useful addition to the resources of the physician. The addition of sugar will, of course, reduce, in most cases advantageously, the proportion of proteids in the food.

SPARKLING NATURAL MINERAL WATER OF
SCHLOSSBRUNNEN GEROLSTEIN.

(GEROLSTEIN WATER COMPANY, PHILPOT-LANE.)

An excellent table water, soft and pleasant to the taste, and possessing mild alterative properties. Alkaline carbonates and sulphates seem the chief constituents. It is obtained from an artesian well in the district of the volcanic Eifel.

SPARKLING HYGEIA.

(R. MCDougALL, 61, ST. PAUL'S CHURCHYARD.)

This is the result of another praiseworthy and successful attempt to vary the monotony of non-alcoholic drinks. "Sparkling hygeia" is a wholesome and pleasant drink, and is not unlike light champagne.

HARZER WATER.

(HARZER NATURAL MINERAL WATER COMPANY, 135, LONDON-WALL.)

This is a soft and pleasant table water. Whether it is better than some other of the new competitors for public favour is more than we can pretend to decide. Their name is legion.

GLENROSA: PURE HIGHLAND MALT WHISKY.

(T. MERRITT & CO., MARK-LANE.)

A pure and soft spirit of good flavour. It is vastly better than most of the Scotch whiskies sold.

THE NEW ROYAL INFIRMARY AT
EDINBURGH.

(Concluded from page 398.)

ABOVE the head of each bed in the ward is a gas-jet, and there are gas pendants also in the centre of the ward. *Every one of these gas-jets is provided with its proper flue, so that when the gas is lighted the air of the ward is not fouled, and the rate of renewal of the air is probably much quickened.* These gas flues travel to the chimneys of the ward. This arrangement is worthy of all praise, and we trust that Mr. Bryce will succeed in convincing his brother architects that it is as unreasonable to neglect to provide proper flues for the gas as it would be to build fireplaces without chimneys. Although there are gas flues in the wards, they are not found in the ward annexes, but why there has been this falling away from the paths of virtue, and why nurses and others in the kitchens and elsewhere are still to be stifled in the old-fashioned way, is not apparent. The number of gas-jets appears to us to be excessive, and on one surgical pavilion floor we counted in all forty-eight jets, or three jets to each patient. These forty-eight jets are capable of burning (probably) something like a thousand cubic feet of gas in five or six hours (between four o'clock and ten in the winter), and we can only hope that gas does not cost 3s. 9d. per thousand cubic feet in Edinburgh.

The walls of the wards are of Parian cement, painted with oil paints. The floors are of deal stained yellow, with a double pathway of floor-cloth. It is a pity so soft a wood was chosen for the floor material, and we could wish that economy had been practised in other parts of the building, in order to lay parquetté floors, which can be done nowadays at a comparatively small expense. The woodwork throughout the hospital is of soft deal. It is gaping already in many places, and we were struck with the inferiority of the woodwork generally when compared with the excellence of the masonry.

A few words as to the sanitary offices attached to the ward. These are mainly in the turrets, and are entered by swing doors at the ends of the wards. These doors are protected by wooden screens, which, as far as we can see, are of no use whatever. The screen prevents the door being fully opened, seriously interferes with the traffic through the doors, and forms a nasty angle with the wall of the ward, where dust will certainly accumulate. What useful purpose

it serves we do not know. One turret is devoted to a bath-room and lavatory, while the other contains a w.c. (with one seat), urinal, and slop-sink. The arrangement is similar in both turrets. The circular chamber is divided into two unequal halves by a wall, and the smaller half serves as a lobby with cross ventilation, giving access to the lavatory and bath in one turret, and to the sink, urinal, and w.c. in the other. Although we said that the Scotch baronial style lent itself very admirably to sanitary purposes, we do not say that it is advisable to give a circular form to a turret devoted to sanitary purposes, and we think it was a mistake not to have the sanitary turrets of the Royal Infirmary larger, and of a different shape. *All ward offices should be placed in the turrets.* In the Royal Infirmary this has not been done, and although we have one w.c., one urinal, one sink, one bath, and two lavatory basins placed in the turrets at the ward end, and cut off by a cross ventilated lobby, we have a ward-kitchen, one sink, one lavatory basin, and one bath placed in that part of the pavilion floor which forms the ward-approach, and not cut off by any cross ventilation at all. Now all the pipes of the sanitary offices have been carefully concealed by woodwork, stonework, &c., and what becomes of them is a matter of hearsay. The soil-pipes have all three-inch ventilating-pipes going to the top of the turrets. Whether the various waste-pipes are ventilated we did not learn, but none of them have been "cut off" according to the modern fashion, but all proceed direct to the sewer. Thus the ward is placed between two sets of sanitary arrangements, and the probability seems to us very great that air blowing from the corridor past the sanitary offices in the ward-approach and through the door of the ward will occasionally have the opportunity of bringing a puff of sewer gas with it. The possibility of such an occurrence (no matter how remote the probability may appear) should not have been allowed to exist in any modern hospital. The sanitary offices in the ward-approach are, we presume, for the use of the two beds in the private ward, and these two beds, be it observed, have an allowance in these matters equal to that provided for the other fourteen beds. Private wards should not, we think, be placed in close juxtaposition to public wards, but should be arranged altogether in a distinct place, with a sufficient, but not an extravagant, allowance of sanitary offices. If the private wards had been arranged elsewhere, and if the turrets had been larger, a great economy would, we believe, have been effected. A certain number of baths and sinks might have been altogether abolished. An additional w.c. might have been placed in the turret (one is not enough for fourteen patients), and the ward kitchen might have been placed there too. Ward kitchens are almost always too big. All the cooking necessary to be done in the ward might be effected by means of a few Bunsen's burners, and it seems ridiculous in the present day to provide a spacious apartment and a kitchen range for boiling water, heating beef-tea or gruel, or, possibly, cooking an egg. A circle of gas jets, together with a sink for "washing up," and a certain amount of stowage-room and pegs for apparatus and crockery, are all that is necessary. By all means let a ward-kitchen be well thought out and carefully planned. Were we asked to design one we should certainly consult the steward of a Cunarder or a P. and O. boat, who could teach hospital architects very much as to the manner in which compactness is often conducive to cleanliness, tidiness, and convenience. Because several thousand cubic feet of space is given to a patient, it is not therefore necessary to give a proportionate amount of space to his plate, mug, and spoon. If the turrets had been larger and of a different shape access to the turret bath-room would have been easier. As it is, to get from the ward to the bath-room in the turret one has to take a circuitous course to the left, round the screen, then obliquely to the right, through two doors only 2 ft. 10. in. wide, and then to the left again, and all within the space of a few feet. It must be no easy matter to carry a helpless patient to the turret bath-room.

It will be gathered that we consider the private wards should have been placed elsewhere, and that the bath-room, kitchen, and w.c. should have been omitted from the ward-approach. It does not seem to us necessary to provide a separate day-room for every ward, and we think it would have been better to have provided common day-rooms for two or three wards, and more removed from the wards, so that a complete change of air might be enjoyed by the patient.

We are almost afraid to touch upon such a burning question as whether a nurse should live close to her ward or away from it, and whether, while she is on duty, her proper course is to remain like a sentinel in the ward itself, or sit in an adjoining room and look through the window of it into the ward occasionally. Those who take the former view would not provide a sitting-room or a bedroom for a nurse in connexion with the ward. It is evident that a nurse is more likely to enjoy real rest during her hours off duty, and to breathe a purer air at such times, if her living and sleeping accommodation is provided for her at some spot remote from the ward itself. It is still almost the universal practice to build nurses' rooms adjoining the ward itself, but we very much doubt if the practice be a good one. If it is to be continued, however, the bottom panes of the nurse's window commanding the ward ought certainly not to be frosted over and rendered nearly opaque, as is the case in the Edinburgh Infirmary. We hold it to be quite as important that the patients should be able to see the nurse as that the nurse should see the patients, and if a nurse can go into a private room where she can neither see her patients nor be seen by them, and yet be considered to be "on duty," we certainly think that these rooms are an evil and not a benefit.

Of the seven rooms which open on the passage of the ward-approach, we have raised objections either to the existence or the position of six. We have now only to deal with the "doctor's room," which is a big room corresponding to the nurse's sitting-room, and contains a fireplace, &c. We do not properly understand the object of this room. There are at least twice as many of these rooms as there are resident officers, and the living apartments for these gentlemen are in George Watson's house. They are not fitted up as if they were intended for chemical or microscopical work, and it would certainly be undesirable to provide such laboratories close to the ward doors. It is not intended to see casual out-patients in, for there are special rooms for that purpose. There are thirty of these apartments in the hospital, and we are in doubt as to the necessity of devoting such an enormous amount of cubic space to a purpose which, to say the least, is not very clearly defined. It will be seen, therefore, that we consider all the apartments of the ward-approach very seriously open to criticism.

In theory, wards like those in the Edinburgh Infirmary are not intended to be ventilated through the door; in practice they must be, and during the depth of winter it may happen that the doorway will serve as by far the most important inlet for air. As this will inevitably be the case, it seems to us undesirable that the air blowing through a ward door should be allowed to pass along a passage and past the doors of rooms containing patients, sanitary apparatus, unventilated gas-lights, cooking stoves, &c. Such air is not likely to be "fresh" air. From a purely sanitary point of view this arrangement is undesirable, and from an economic point it seems still more so, for not only is the cubic space devoted to the work done in these approaches far in excess of what would be necessary were the arrangements different, but the number of fireplaces, gas-lights, &c., for lighting and warming is excessive also. Too much cubic space where it is not needed (and, mind, we find no fault with the amount in the ward itself) means not only a serious increase in the cost of building, but a serious increase also in the cost of cleaning, lighting, and warming. On each ward floor there are no less than eight fireplaces, and three hot-water coils (one in the approach passage and one in each turret), together with forty-eight gas jets as mentioned above. This is the allowance, be it remembered, for sixteen patients. In the larger medical pavilions there are nine fireplaces, there being four in the ward itself.

We are next going to raise the question as to whether or not it is desirable to unite every part of a "pavilion hospital" with every other part by means of a closed corridor. The corridors of the Royal Infirmary are glazed on both sides, and heated throughout by hot-water coils. There are twelve of these coils in the lower surgical corridor, and there are, we believe, about four miles of steam-pipe throughout the building. This arrangement is very luxurious and very comfortable no doubt, and the corridors will make a charming lounge for convalescents and others; but it is obvious that these horizontal corridors, upon which the vertical lifts and staircases open, completely do away with the grand principle of isolation. We hold that an officer making the round of a pavilion hospital should consider himself in the light of a person walking about a village, and the great aim of the architect should be

to compel every person who passes from one ward to another to go into the *open air*. Of course the corridors should be covered, and there might very well be protection from wind, but to have them completely closed we believe to be an error. Officials would very soon get accustomed in the winter to wear warm out-door clothing when walking about the building, and convalescent patients would do the same, and we believe that it would be conducive to the health of all concerned. In such a building as the Royal Infirmary it would be an easy matter to provide a special warmed and glazed corridor, with a southern aspect, as a recreation-ground for consumptive patients in the winter. The corridors are twelve feet wide, and this appears to us to be an extravagant width. The main surgical corridors enclose over 170,000 cubic feet of space. Had the width been eight feet instead of twelve, a saving of over 50,000 cubic feet of space would have been effected; and be it remembered that the cost of a building is proportioned to the number of cubic feet contained. In order to provide healthy wards for patients, it is not necessary to give every part of the building the proportions of a palace.

The number of staircases seems to us to be excessive. There are eleven of them in the building. By placing the staircases in the pavilions, it is, of course, necessary to have a separate one for each pavilion. We think a much better plan would have been to place the staircases outside the pavilions, so that the air of one pavilion floor could not possibly drift upwards to the next. If the staircases and lifts had been placed (the latter inside the former) midway between the pavilion and communicating with *open* corridors, the isolation of the separate pavilions and of each separate floor would have been *real* instead of only apparent, as is now the case; and we believe that four staircases and four lifts would have then served the building as well as more than twice that number, which is at present necessary, and would have proved sufficient. *Sufficiency* should be the aim of hospital constructors, and we hold that to provide either more or less than a sufficiency is an error. Many of these points are by no means peculiar to the Edinburgh Royal Infirmary, and the only fault we can find with the planners of it is that they have copied what we believe to be the mistakes of their predecessors in hospital construction. At St. Thomas's, at the new Hôtel Dieu, and elsewhere, the idea seems to have been held that a hospital, in order to be wholesome, must be magnificent, even in points where magnificence is of no earthly use to anybody. In the Edinburgh Royal Infirmary the managers have avoided all wasteful ornamentation, but they have fallen into the error of giving magnificent proportions to parts of the building where size only means expense in construction and maintenance, and difficulty in cleansing.

A few words concerning the attic storey of the pavilions. This is reached by a narrow wooden staircase, and the part over the ward-approach is devoted to the sleeping accommodation of the "ward assistants." These sleep partly in cubicles and partly in separate rooms. The roofs of these attics slopes, so that the height varies, and they are heated with hot water. One of these cubicles measured 6 ft. 9 in. by 13 ft. 6 in.; they each contain therefore about 40 square feet of area, and no artificial means, as far as he could see, of renewing the air in it. There is accommodation for a great many more ward assistants than actually exist, and many of these cubicles will probably be never used as sleeping apartments, which may be considered fortunate; but why, it will be asked, was the expense of their construction ever incurred? There is a bath and w.c. in each of these attics. The one we visited was not very clean, and a damp garment was hung over the stairs to dry. It did not impress one as either an attractive or a wholesome region. Over the ward itself there are no cubicles, but merely the foul air extraction pipes and a passage for workmen.

We may now leave the pavilions, and give a brief description of other parts of the hospital. The old building of George Watson's Hospital (shaded dark in the plan) is occupied by the resident students in the eastern wing, and by the nurses in the western wing. Here is also the chapel and the kitchen. The clinical lecture theatres and the big operating theatre (marked C and O)¹ are all first-rate, being well lighted and very well contrived. The operating theatre has skylights to the north and south, and a side light facing the north. (We may have a word to say in another place concerning the operating tables and the special tables for the

¹ For plan, see p. 396.

steam spray.) The two projections from the main building marked x and y in the plan are a student's room and a casualty-room. Running beneath all the corridors and all the pavilions is a subterranean passage, in which are the coal-cellars, and to which all the various shoots and lifts and staircases descend. The hot-water pipes travel along the ceilings of these passages, and the heated air in it has a tendency to ascend into the building. On that account it will be very necessary to attend to the purity of the air in this passage. There is a special passage leading underground to the mortuary and the pathological department, so that the dead, in their transit to the deadhouse, are as little as possible exposed to the gaze of the living. The fixing of the big hot-water pipes in the vaulted summit of this passage has rendered it just not high enough for the safety of the heads of porters of average size who may have to work in it. Beneath the southern ends of the south (medical) pavilions are day-rooms for the patients. We may notice, in passing, the existence of a dry shed for the carriages of the staff while waiting for their owners, and a lawn tennis ground for the residents. In such a huge building, occupying several acres of ground, the means of ready communication are quite necessary, and we believe that it has been arranged to place every part of the building in telephonic communication with the others. There are suitable waggons for the coals, and admirable trucks (designed by Surgeon-Major Fasson, the superintendent of the infirmary) for the dinners. These trucks have a metal lining which is filled with hot water, while the interior is occupied by specially-designed tins, and in point of fact the patients get their dinners as hot as possible, notwithstanding that the distance from kitchen to wards is rather great. The centre building (marked A on the plan) is occupied by an entrance hall, treasurer's office, board-room, &c. Here, also, are some special wards set aside for ovariectomy, and at the top of this building are the female "Lock" wards; while in the clock tower itself, reached by a stone spiral staircase, up or down which no patient could possibly be carried, is a room for examining and operating upon female patients suffering from venereal disease. This last room is an instance (and we are bound to say that such instances are not common in this building) of how matters of internal convenience have occasionally to give way to the external style of a building.

There are no separation wards in the new infirmary for contagious or infectious cases. The infirmary drains into the town sewers, and the managers are under an obligation not to discharge the sewage from infectious patients into their drains. For the present the old infirmary building is used for infectious cases, and when this building is sold some fresh arrangement will have to be made.

Besides the main building, which we have described at, we fear, a tedious length, there are certain subsidiary detached buildings which need to be mentioned. There are two entrance lodges on the north side; a house for the superintendent has been provided on the east side, facing Meadow-walk; while on the north-west side of the ground are the laundry, the boiler-house, the mortuary, and the pathological department. The laundry is not yet complete, and the boilers and heating apparatus are not yet quite out of the hands of the contractors. A huge chimney belching smoke, however, already indicates that scientific institutions are as little able to accomplish a complete combustion of fuel as are the most ignorant of mill-owners. The pathological department is very complete and well appointed. The post-mortem theatre appears to be well planned, and fitted with every convenience. We were particularly struck with the construction of the post-mortem tables. These are of slate, revolving on an iron pivot, the pivot also serving the purpose of a drain. Above each table is a circle of gas-jets for use in winter, and from the centre of this circle comes the flexible tube for the supply of water, a combination of gas-pipe and water-pipe being so arranged that one pipe appears to serve both purposes.

The total cost up to the present time of the buildings, site, and furniture, has been about £340,000. The total number of patients' beds is 570.

In conclusion, we have to acknowledge the great courtesy received from everyone to whom we have applied for information concerning the building which we have been describing. To Mr. Peter Bell, Surgeon-Major Fasson, and Mr. Bryce, the architect (who furnished us with a sketch-plan, and gave us much of his valuable time as well), we are especially indebted. We have, it will be observed, dealt with the subject in a purely critical spirit. Many of

the points to which we have taken exception are not peculiar to the Edinburgh Royal Infirmary, but are common to most "pavilion hospitals" which exist at present. It is because we believe the pavilion hospital to be susceptible of much improvement that we have been at the pains of using the most recent of them as a means of pointing out what we believe to be the shortcomings of this class of buildings. Many of the points we have raised are no doubt fairly arguable. We have raised them in the interest of those who inhabit, build, and work in hospitals. The Edinburgh Royal Infirmary is certainly one of the finest and best hospitals in the country, but it would be a mistake to regard it as perfection, and for future hospital builders to be content with merely imitating it.

LUNACY REPORTS FOR 1879.

THE issue of the Thirty-fourth Annual Report of the English Commissioners in Lunacy affords the best available materials for considering the proportion and distribution of lunacy in England and Wales during 1879. The total recorded number of lunatics, idiots, and persons of unsound mind in England and Wales on Jan. 1st last was 71,191, showing an increase of 1306 upon the registered number on the first day of 1879. Presuming the proportional prevalence of lunacy to be stationary, it is evident that the number of lunatics in a rapidly increasing population, like that of England, would steadily increase. It is impossible, therefore, to judge of the increase or decrease of lunacy without taking into account the proportion of lunatics to population. In the second table of the lunacy report just issued, it appears that the ratio of registered persons of unsound mind has continuously increased from 18·67 per 10,000 in 1859, to 27·94 on the 1st January last. The proportion, which was 18·67 per 10,000 on the first day of 1859, and 23·93 at the beginning of 1869, further rose to 27·77 on January 1st, 1879, while it was, as before stated, 27·94 on the first day of this year. Without attempting now to discuss how far the true increase or decrease of lunacy in England and Wales can be estimated from the recorded numbers of persons certified or returned as of unsound mind by a variety of authorities, it is well to note that the proportion of lunatics and idiots to population showed an average annual increase of 2·8 per cent. in the ten years 1859 to 1869, while in the second decade 1869-79 the annual increase in the proportion did not average more than 1·6 per cent.; the increase per cent. during 1879 did not exceed 0·6 per cent. There is a marked decline, therefore, in the rate of increase of the registered insane, which if maintained must soon turn the increasing to a decreasing rate. If it were possible to make due correction in the returns for the effect of more complete registration and report of cases of lunacy in recent years, owing partly to the tendency of public opinion in the direction of in-door instead of out-door poor-law relief, and partly to the State aid which in recent years has been given towards the cost of lunatics in asylums, it is doubtful whether the apparent increase of lunacy would not disappear. One of the most important considerations with reference to lunacy, regarded as a disease, is its distribution or varying incidence in different localities and populations. The lunacy report, however, does not afford satisfactory materials for the study of this part of the subject. It is true that tables are given showing the registered number of pauper lunatics in each of the counties of England and Wales; the reader, however, is left to calculate for himself the proportion of lunacy to population in the several counties, which is the only true measure of lunacy. It is unfortunately impossible to distribute private lunacy to the different counties, and we are therefore driven to accept the proportions of pauper lunatics as a measure of the prevalence of lunacy. We have noted that the total proportion of lunacy, private and pauper, was equal to 27·9 per 10,000 of the population in England and Wales on 1st January last. If we exclude the private lunatics we find the proportion of pauper

lunacy to be 24.9 per 10,000. We have been at the trouble to calculate this proportion of pauper lunacy in the different counties, and find the usual wide variations. London—that is, registration London—continues to show the largest proportion of lunacy, equal to 36.3 per 10,000. This excess of registered lunacy in the metropolis affords the strongest evidence that liberal provision of asylum accommodation has a marked tendency to promote the registration of lunacy. In no other part of England and Wales is the provision of asylum accommodation so proportionally large as in the metropolis; this is mainly owing to the erection of the asylums for idiots and harmless lunatics at Leavesden, Caterham, and Darenth. In England and Wales, exclusive of the metropolis, the proportion of pauper lunacy did not exceed 23.0 per 10,000, against 36.3 in London. The proportional incidence of pauper lunacy shows marked variations in the several counties; the proportion per 10,000 of the population did not exceed 13.6 and 15.6 in Durham and Stafford, whereas it ranged upwards to 35.0 in Wiltshire, 35.3 in Oxfordshire, and 37.4 in Herefordshire. We may probably return to the discussion of lunacy distribution in England and Wales, but will note in passing that, contrary to most other diseases, lunacy shows the greatest prevalence in agricultural populations, and the smallest prevalence in those counties in which the proportion of urban population is the largest. On the 1st of January last 64.7 per cent. of the pauper lunatics in England and Wales were in asylums, hospitals, and licensed houses; 25.9 per cent. were in workhouses (including the inmates of the asylums at Leavesden, Caterham, and Darenth); and the remainder, or 9.4 per cent., were residing with relatives or others. In 1859, no less than 18.2 per cent. of pauper lunatics were residing with relatives or others; since then this proportion has steadily declined. If the imbeciles at Leavesden, Caterham, and Darenth be included with the inmates of other asylums, the proportion of the insane under treatment in special institutions at the beginning of this year becomes 71.7 per cent., and the proportion retained in workhouses, which was 25.1 per cent. in 1859, is reduced to 18.9. The proportions of pauper lunatics maintained in asylums, in workhouses, and residing with relatives and others in the various counties of England and Wales, show marked variations, which want of space forbids us now to discuss. It may be pointed out, however, that only 55.0 per cent. of the pauper lunatics in Gloucestershire, and 55.9 per cent. in Nottinghamshire, were under treatment in asylums at the beginning of this year, and the proportion of lunatics residing with relatives and others was so large as 17.2 per cent. in Norfolk, 17.6 in Wiltshire, and 21.0 in Herefordshire. We shall defer to another notice a discussion of the rates of mortality prevailing among the insane during last year, but regret to find that the report just issued affords no more satisfactory materials for its discussion than previous reports. The approximate ages of the insane population and of the decedents is absolutely essential, in order to arrive at the true excess rate of mortality due to insanity. For this purpose the ages of the insane admitted to asylums in a single year are comparatively useless. We have on more than one occasion expressed our conviction of the complete futility of the information given in recent reports on so-called causes of insanity. These statements, often little better than mere guesses, are worse than useless as a guide to the scientific study of the true causes of insanity.

From a statistical point of view the Twenty-second Annual Report of the General Board of Commissioners in Lunacy for Scotland is, in many respects, superior to the report recently issued by the Commissioners for England. Not only are the tables more complete and better arranged, but in the report itself the statistics are more thoroughly discussed and turned to account. In one respect, however, we regret that the Scotch figures are as defective as those in the English report. No information is given as to the ages of the registered lunatics, or of the ages of the decedents; and without such information it is impossible to obtain completely satisfactory mortality statistics of the insane population. It may be hoped that the Scotch Commissioners may see their way to give information on this point in future reports. The most complete statistics of lunacy which have come under our notice are those somewhat recently issued by the Metropolitan Asylums Board, relating to the inmates of the asylums at Leavesden, Caterham, and Darenth during 1879. The Commissioners in Lunacy, both for England and Scotland, will do well, when their next reports are under preparation, to incorporate a few of the tables on this branch of

the subject from the Leavesden and Caterham reports. It appears from the Scotch report that on the 1st January last the registered number of lunatics was 9624, showing a further increase of 238 upon the numbers at the beginning of previous years. The number of lunatics to 10,000 of the population was 25.8, against 27.9 in England and Wales. This proportion of registered lunatics has steadily increased year by year from 19.2 in 1858. In one respect the Scotch statistics of lunacy differ materially from those for England and Wales. We have shown that in England the rate of increase of lunacy is a decreasing rate; in Scotland, however, an ascending rate of increase still prevails. The increase during the five years ending 1870, compared with the preceding five years, was equal to 4.8 per cent.; while in the two succeeding quinquennials, ending 1875 and 1880, the increase was respectively 6.5 and 8.7 per cent. The Scotch statistics bearing upon the distribution of lunacy compare most favourable with the meagre materials on this branch of the subject in the report of the Commissioners for England. In the Scotch report is given a complete and well-arranged summary of the proportional amount of pauper lunacy in each of the counties during the twenty years ending 1880. It appears that the annual average of pauper lunatics per 10,000 of the population during the last quinquenniad, 1876–80, ranged in the several counties from 6.9 and 9.6 in Selkirk and Shetland to 25.8 in Bute, 25.9 in Argyll, and 29.9 in Kinross. The difficulties, however, in the way of a useful comparison of the statistics of single counties are very properly urged in the report before us, and the statistics of two groups of counties, Highland and Lowland, are suggested for comparison and consideration. The proportion of the insane of all classes on January 1st, 1879, was equal to 31.6 per 10,000 of the population in the Highland counties, whereas it did not exceed 20.1 in the Lowland counties. This marked excess of lunacy in the Highland and more purely rural population corresponds with the result of similar comparisons in England, where, if we exclude the metropolis, we find a far greater ratio of insanity prevailing in the rural counties than in those counties in which the largest proportions of the population are urban in character. We can only on the present occasion refer to one other branch of the subject as dealt with in the Scotch report, the proportional asylum and other treatment of the pauper insane. On January 1st last, of the 7957 registered pauper lunatics, 4569, or 57.4 per cent., were in Royal and district asylums; 1229, or 15.4 per cent., in parochial asylums; 676, or 8.5 per cent., in workhouse lunatic wards; 1415, or 17.8 per cent., in private dwellings, and 68 in training schools. The main point of difference between these proportions and those prevailing in England consists in the fact that 17.8 per cent. of the pauper lunatics in Scotland were residing with relations and others, and were under no kind of control or efficient supervision, while the proportion similarly conditioned in England did not exceed 9.4 per cent. at the beginning of this year. We shall have occasion again to refer to this subject when we consider the varying results of treatment in asylums and otherwise, with reference to proportional recovery and mortality.

CHARTERHOUSE SCIENCE AND ART SCHOOL AND LITERARY INSTITUTE.—The Winter Session of this, the largest Science School in the United Kingdom, will, under the continued presidency of the Rev. J. J. Rodgers (V.C. of the London School Board), commence on Saturday, the 25th of September. During the late Session about 800 students availed themselves of the privileges afforded by this Institution, and of this number nearly 600 presented themselves for examination and were successful in obtaining no less than 140 Queen's Prizes awarded by the Science and Art Department of South Kensington. At a nominal fee instruction of a practical character is given in most of the sciences, whilst in Art, at an equally low rate, students, under the direction of four competent instructors, can be advanced in their studies. Those who aim at becoming proficient in Chemistry (Organic and Inorganic) have the opportunity of working in a well-fitted laboratory capable of holding sixty students. Aspirants for University honours can, at a small expense, be assisted in their studies. Lessons in Latin, Greek, French, German, and Music are given by well qualified teachers. Full particulars can be had of the Organising Secretary, Mr. C. Smith.

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 18, 1880.

THE present condition of the Medical Service of the Royal Navy requires the immediate and careful consideration of the Admiralty, and we trust that when Lord NORTHBROOK returns from his well-earned holiday he will investigate thoroughly the causes to which its decadence has been due, and by judicious measures endeavour without delay to restore it to a state of efficiency. At the two examinations in 1879 only fifteen candidates came forward to supply somewhere about seventy vacancies, and at those held in the present year only ten presented themselves. That it is the duty of the Government to provide an adequate number of duly qualified medical officers to attend the officers and men of the Navy in sickness and war and to keep a vigilant watch over their health with a view to prevent disease will, we doubt not, be universally admitted. The question, then, is, What are the causes of the unpopularity of the Service? and what means must be adopted to render it more acceptable to the younger members of the profession? Among the principal causes which prevent candidates from coming forward, and which give rise to discontent among the officers in the Service—a discontent which reacts on the medical schools—may be mentioned the lower rates of pay and retirement than those now given in the Army; the loss of time arising from the system of compulsory half-pay when ships are paid off; the practical denial to medical officers of “cabins according to their relative rank,” as laid down in the Orders in Council; and the rule requiring five years’ service in the rank of Deputy before being eligible for promotion to Inspector-General of Hospitals and Fleets. To render the service popular and to attract a good class of medical men to come forward as candidates a thorough reorganisation of the Department seems necessary. The rates of pay and half-pay must be brought up to an equality with those in the Army; the advantages granted by the Orders in Council must be secured to the medical officers, and stringent rules laid down to prevent them, as at present, being evaded. Hitherto an attempt has been made to remedy the evil of compulsory half-pay by allowing four years’ full pay service to count as five towards retirement; but this is at best an unsatisfactory compromise; it does not compensate the unlucky officer who has more than his fair share of half-pay, while it gives an additional boon to the fortunate men who have interest at the Admiralty. The best mode of dealing with this grievance would be to abolish the compulsory half-pay by sending the medical officer, after a reasonable period of leave, to do duty in one of the naval hospitals till his services are again required afloat. We see no reason why this should not answer in the Navy as well as it did in the Army when the regimental system was in operation. When a regiment returned from foreign service, the supernumerary medical officers were not placed on half-pay, but were sent to the General Hospital at Fort Pitt, unless their services were required elsewhere. If,

however, so great an innovation does not find favour in the eyes of the Lords of the Admiralty, some plan should be devised by which the actual half-pay time of each officer might be credited to him, instead of the average of the whole service being divided equally among the lucky and unlucky. Besides these changes, it would only be just to create in the Navy a grade between the Fleet Surgeon and Deputy Inspector-General, corresponding in pay and retirement with the Brigade Surgeon in the Army; and if this were done, the age for the compulsory retirement of Fleet Surgeon and of this new rank might advantageously be made fifty-five instead of sixty, thereby giving more hope of promotion to the juniors. The rule to which we have alluded, of five years’ service as Deputy Inspector-General before being eligible for promotion to the higher rank, should be abolished. It seems very unjust, and the absurdity of it was recently shown in there being no officers eligible to fill several vacancies of Inspectors-General; indeed, it became necessary to promote the present Director-General without his having ever served as an Inspector-General. No such rule exists in the Army, and we can see no reason why it should in the Navy. An officer who has risen through the junior grades, and has been selected as eligible for the appointment of Deputy Inspector-General, must surely be fit to undertake the duties of Inspector-General without going through a five years’ training in the lower rank. We presume it was originally introduced as a means of saving money, but it is a very miserable economy which is effected at the expense of justice, and must naturally give rise to discontent. Lord NORTHBROOK is very capable of taking a large and liberal view of the requirements of the Service, and we have every confidence that he will do so. We would only remind him that the sooner a remedy is applied to so very unsatisfactory a state of matters, the more advantageous it will be to the Service and the more creditable to himself as a statesman.

THE influences which determine the condition of the blood-vessels, their dilatation or contraction, are of extreme importance. Current opinions of the nature of these influences have largely dominated theories of both healthy and morbid action, and every new fact regarding them is of the greatest interest to both the physiologist and the pathologist. A series of investigations by Dr. W. H. GASKELL, which have been carried on in the physiological laboratory at Cambridge, and lately described to the Royal Society, constitute an important addition to our knowledge, and furnished the subject of one of the most interesting demonstrations given at the recent meeting of the British Medical Association. Although their greatest interest is in relation to the peripheral vessels, the observations deal primarily with the states of the heart. Complex as the mechanism of cardiac action is, the apex of the frog’s heart presents much more simple conditions, in that it is, so far as has been ascertained, destitute of nerves or nerve-cells. It thus presents a favourable object for the investigation of certain phenomena of vascular action. It has been hitherto believed that all inhibiting or dilating influences on both heart and vessels depend immediately on the nervous system. In accordance with this view, if the nerveless lower part of the ventricle of the frog is physiologically separated from the

upper part by a ligature, it ceases to beat, even though, by a cannula previously introduced, the frog's own blood is supplied to it. But MERONOWICZ has found that if an artificial blood solution is supplied to it, or it is stimulated by the constant current, this nerveless apex will recommence its rhythmical contractions; and FOSTER has further ascertained that the same effect is produced when the heart is supplied with the frog's own blood, but the pressure of this is increased, as by clamping the aorta. Hence, if the stimulation afforded by a mere increase in the intracardiac pressure will induce rhythmical contractions in a nerveless heart, we must regard the view that the action of the muscular walls of the vascular system depends solely upon nervous influence as at least open to reconsideration.

It has been lately ascertained that a dilute alkaline solution will re-excite contractions in the isolated and quiescent apex. This effect was ascribed to the removal of some obstruction. But the suggestive fact has been ascertained by GASKELL (employing ROY'S tonometer, by which variations in the size of the cavity are recorded) that the contractions so excited are presently arrested by the heart passing into a condition of tonic spasm. The relaxation between successive beats becomes less and less, and the heart apparently stops in systole. It is not a state of tetanus—i.e., of rapidly-recurring contractions,—but apparently one of “idio-muscular” contraction or tone. If a saline solution is passed through the heart, it will frequently remain without beating, and then sometimes the alkaline solution may be observed to cause a gradual tonic contraction without any rhythmical beats. It was next found that a dilute acid solution (of lactic acid) had an action precisely opposite to that of a dilute alkaline solution. The ventricle was quickly brought to a standstill in the position of complete relaxation. The effect of neither acid nor alkali is permanent; in either case artificial blood solution is able, subsequently, to cause contraction differing in no way from the normal. The actions of the acid and alkaline solutions are not merely opposite, they are actually antagonistic. If, by means of an acid solution, the beats have been lowered in force, they are quickly restored to the normal by an alkaline solution, and *vice versa*. Dr. GASKELL has further ascertained that certain poisons act on the heart as does the alkali, while others act as acids. Thus antiarin (the poison of the upas tree) and digitalin act as do alkalies, causing an increased tone, irrespective of contractions—a tone which ultimately renders contractions impossible. Muscarin, on the other hand, acts as the acid. Pilocarpin also acts like the acid, while atropin acts in the same manner as the alkali.

Further investigations have brought out the important fact that alkaline and acid solutions act upon the muscles of the smaller arteries in the same way as upon the cardiac muscle. The observations were made upon the mylo-hyoid muscle of the frog, after pithing, and division of the mylo-hyoid nerve, to eliminate all nervous influence. Solutions were sent through the vessels at a constant pressure, and provision made that the modification in the heart's action should have no effect on the pressure in the vessels. The lactic acid solution produced always an enlargement in the calibre of the arteries, and the flow through them was proportionately more rapid. The alkaline solution caused invariably a diminution in size, usually to absolute closure,

with a corresponding obstruction to the flow through the vessels. Moreover, the same antagonism of the two solutions was found to exist for the vessels as for the heart. Although lactic acid was employed in these experiments, it was ascertained that the effect of acetic acid was exactly the same.

Hitherto, as we have said, the condition of the heart and smaller bloodvessels has been regarded as dependent solely on the influences exerted through the vaso-motor nervous system. These experiments show that local influences, the nature of the fluid surrounding the muscular fibres, also affect their condition. Their tonicity is augmented by the increased alkalinity of the fluid, is diminished by its lessened alkalinity. Functional activity is everywhere attended with vascular dilatation, by the mechanism, it has been hitherto assumed, of the vaso-motor nerves. But if the state of the muscular tissue of the vessels may be modified so largely by the fluid around them, may not the products of the activity of the organ determine, by local action, the dilatation of the vessels? Dr. GASKELL ingeniously argues that it is *a priori* probable that it may be so, from the structure of the vessels, the muscular fibres lying immediately *outside* the impermeable elastic lamina. It is in the highest degree probable that the lymph fluid of muscles is rendered less alkaline by the chemical products which result from muscular action. In the brain and pancreas the same conclusion is also probable from recent researches, and these facts suggest that it is true of all tissues. According to some investigations by KLUG, oxygen strengthens, carbonic acid lowers, the cardiac pulsations, and alkalinity promotes oxidation. It is probable, then, that throughout the whole vascular system normal tone and rhythmical action are dependent in part upon the due oxygenation and alkalinity of the fluid supplied to its muscular tissues, while, on the other hand, the tonicity cannot be maintained or the rhythmical action continued, when that fluid is overcharged with such products of tissue metamorphosis as lactic and carbonic acids.

Besides its visible pulsations, the muscular tissue of the heart varies much in its condition of tone, as these observations demonstrate. If in the normal state the relaxation between the separate contractions is nearly complete, and the cavity closed for a definite time at each contraction, then with a greater tonicity, the period of closure would be longer, the intermediate dilatation would be less complete. With less tone, the cavity would be closed for a shorter time, or incompletely closed at each contraction, and the diastolic relaxation greater. To the latter condition, long recognised theoretically in cardiac pathology, BEAU many years ago gave the inexact term of “*asystolie*.” When the ventricle of the frog is tied, atony is produced; the alkaline blood solution gradually improves its tonicity, as tracings show, until spontaneous pulsation result.

It is unnecessary to point out how immediate and important is the application of these facts to the physiology and pathology of the whole vascular system. It is clear that many phenomena now believed to be produced by the agency of the nervous system may be really independent of it. The vaso-motor nerves exert their influence, profound and extensive, but the tissue elements which they control have also a power of independent action. To determine the relative potency and place of the two modes of vaso-mus-

cular influence, and the relation between their excitants, must be the next steps in the solution of the problems opened up by these researches. The facts already ascertained are of the highest importance and suggestiveness, and, elicited as they are with great care and by a most difficult investigation, their discovery does the highest credit to English physiology.

THE question of bogus degrees admits of facetious treatment, but it is a serious matter. And the United States will do well to take this view of it. We lately remarked with satisfaction on several indications that in America the leaders of medical education are bent on the introduction of reforms both in education and in the examinations by which it is tested. The best schools are forming themselves into an association from which all schools will be excluded which do not insist on a preliminary examination before the commencement of medical education. The period, too, over which medical education is to extend is being lengthened to something more nearly appropriate to the extent of work to be done. This action on the part of the medical teachers in the States cannot be too highly praised or too much encouraged. It is especially necessary in a country whose universities and schools are more or less private institutions, where they spring up like mushrooms, and where a charter is to be had almost for the asking, and once given cannot without much difficulty be withdrawn. There is a large and powerful party in the States who appreciate Protection as a principle. We commend to them a scheme for securing protection to the public against ignorance clothed in the garb of knowledge. Ignorance pure and simple may be left to itself. It is its own cure, and sufficiently repels by its vulgarity and its helplessness. But ignorance put hastily through the schools and diplomatised, and coming forth at the end of a year or two with all the airs of the schools, is a deadly business from which every civilised State should protect its citizens. And this we take to be the lesson which certain of the American medical teachers are trying to impress on the American Legislatures, and, failing that, on the medical profession, which must be its own protector.

The exposure of the system of bogus degrees by the able and energetic action of the proprietor and city editor of the *Philadelphia Record* ought to be of the greatest service to friends of medical education in the States. It is not creditable to the Authorities that this system has been practised for years, and openly advertised, without any effective action on the part of the State whose honour was mainly concerned. To our knowledge, it has been a matter of regret and shame to the able Minister of the United States in this country, and to the many American members of the profession who visit our shores and bring evidence that there are good medical schools and teachers in the States. Not only have degrees in Medicine—and, alas! in Divinity too—been sold, but the enterprising promoters of this trade have bought up the charters of other universities, institutes, colleges, &c., so as to do its disgraceful business on a larger scale. Anyone who doubts this should read the account of this system which is to be found in a book lately published, and containing much information, entitled "Medical Education and Practice," by HERBERT JUNIUS

HARDWICKE, M.D. The following, according to this authority, was the offer of T. B. MILLER, Dean of the Philadelphia University of Medicine and Surgery, to the representatives of the *Record* who applied to him to know how they might become doctors, never having attended lectures, and of course having no diplomas. After stating the cost—100 dollars—and his ability to give a diploma entitling to practise that no man would question, and offering to put the seal of the University of Philadelphia on it, he added:—

"Yes, or you can take your choice of three charters. We have the charter of the Philadelphia Institute of Medicine and Surgery; that was the original charter. Then we have the charter of the Quaker City Business College of Arts and Sciences, which is the best of all. And two weeks ago we bought the charter of the Penn Medical University—that college up on Brown-street, near Thirteenth. They're running yet, but it is without a charter, as they sold it to us."

Taking up a large minute-book, and finding the charter of one of these institutions, and reading Sections 3 and 4, he said:—"That gives us power to confer any degree. We can confer degrees of A.B., A.M., D.D., or anything you want."

Yet, for all this, the State which has been so dishonoured by the traffic in medical degrees and university charters has been either helpless or indifferent, and the criminal has been tracked and brought to light mainly by the efforts of the editor of a Philadelphia journal. It remains now to see whether the legal authorities have the power or the will to deal with one of the greatest and most injurious frauds which can be practised on a community—the sale of degrees in medicine without exaction of guarantees of knowledge, either in the shape of proofs of education or of examination. There is one great branch of this trade, the degrees in Divinity, which if not more injurious to a community is at least more offensive, and which, alas! has had some support from purchasers in this country. One would have thought that as it takes two persons to complete a sale, the sale of degrees in Divinity would have been a scandal which the world might have been spared. The man whose business it is to hold up to admiration "*quæcunque sunt vera*," surely should keep himself from the taint of such a traffic. But even the profession of Divinity has its unworthy members. We must leave them to public judgment, only remarking that there are State reasons for objecting to "doctor factories" which do not apply to institutions for the manufacture of divines, offensive as they are.

A contemporary has treated the capture of the principal criminal in this bogus degree system with a good deal of facetiousness and humour, gently suggesting that there are some analogous processes, not to say trades, even in our country. We will not insult any diploma- or degree-granting body in this country by comparing their too easy grants of degrees and diplomas with what takes place under the system we are now commenting on. We shall, however, take an early opportunity of noticing, as we have noticed before, some parts of our British system of medical qualifications which will certainly deserve the attention of the Lord President or of Mr. MUNDELLA when they come, as we hope they soon will, to complete the work of amending the Medical Acts, which was well begun by the late Ministry.

Annotations.

"No quid nimis."

THE LICENCE OF THE ROYAL COLLEGE OF PHYSICIANS.

STUDENTS who commenced their career after the 25th of March, 1880, should remember that by recent changes in the regulations for the licence of the Royal College of Physicians of London, the examination is now divided into *three* parts. For the first, candidates may present themselves as soon as they are registered according to the requirements of the Medical Council, and can produce evidence of having received instruction on the subjects of that examination. The second examination, on Anatomy and Physiology, takes place after eighteen months of professional study at a recognised medical school; and the third, or final examination, on Medicine, Surgery, and Midwifery, on the completion of four years of professional study. Chemistry and Materia Medica were, until this year, subjects of the final examination; now they are subjects of a separate examination, to be passed early in the student's career, and under circumstances much more favourable to him than heretofore.

HOSPITAL ETIQUETTE AT MANCHESTER.

ONCE again we have our attention drawn, in a letter by Mr. Ewart, printed in another column, to strange doings at the Pendlebury Hospital for Sick Children. This institution, which is so admirably situated and adapted for its purpose, seems to have a Nemesis overshadowing all its work, and bringing its authorities into constant conflict with the sentiments of the profession. This time it is not a member of its own staff that is the aggrieved party, but a member of another hospital staff. The facts may be summed up thus:—A boy, suffering from stone in the bladder, is admitted into St. Mary's Hospital, Manchester, and whilst awaiting operation contracts scarlet fever. By direction of the sanitary authorities, he is transferred to the Pendlebury Hospital—the recognised institution for the reception of children suffering from fever. He is not only cured of his fever there, but also relieved of the ailment for which he had been under surgical care at St. Mary's, and this notwithstanding the assurances given on his transfer that as soon as he had recovered from the fever, he would be sent back whence he came. We need not follow our correspondent through all the stages of this business, of which he has given us a clear account; but we cannot help expressing our surprise that the director of Pendlebury Hospital should not have acted with more circumspection. So far as we can judge, no blame can reasonably be attributed to the surgeon who did operate. We should be sorry to think that any surgeon should be so imbued with the greed of operating as to snatch a chance case, which fell in his way, from a fellow-surgeon's hand, and we do not believe it was so here; for he found the case at his hospital, and it was no business of his to inquire where it came from. Yet there remains behind an unpleasant sense of sharp practice, or convenient forgetfulness, on the part of some one, for how did the Pendlebury surgeon know of the case unless he was invited to take charge of it? As a rule, of course every hospital may claim to treat every case in its entirety, without any restrictions; but, under the circumstances, we must agree with our correspondent that there has been an apparent lack of courtesy in the whole proceeding which should never be allowed to enter into dealings between hospital staffs. Let us hope that the matter has been one of misunderstanding merely, and not of wilful intent to keep a "good case," no matter how, or under what conditions, introduced, into the

hospital wards. Mr. Ewart's letter calls for, and we hope will receive, a frank explanation from the responsible parties at the Pendlebury institution.

SCHOOL-BOARD SCHOOLS AND SCARLET FEVER.

It is impossible to doubt that schools have again and again become sources of contagion for the dissemination of scarlet fever, diphtheria, and other diseases of an infectious character. This undoubted fact suggests the importance of active co-operation between Education and Sanitary authorities, with a view to minimise the unavoidable danger arising from the congregation of increasing numbers of children in our elementary schools. It is to be regretted, however, that assertions are sometimes made which cannot be supported by the inexorable logic of figures. Recently, in reporting upon a local epidemic of scarlet fever, it was asserted, in explanation, that the rate of mortality from scarlet fever in England and Wales had considerably increased since the Education Act of 1870 was passed. There is so much probability of this assertion being accepted as true, that it is worth while to examine carefully the real state of the case. During the ten years 1861–70, preceding the passing of the Education Act, the annual death-rate from scarlet fever in England and Wales averaged 98·8 per 100,000 of the population; whereas in the past nine years of the current decade the rate from this disease has not exceeded 73·1 per 100,000. It is, therefore, beyond doubt that the mortality from scarlet fever in England and Wales since the passing of the Education Act has been 26 per cent. lower than the rate which prevailed in the preceding ten years. As it is thus clear that there has been a marked decrease in the fatality of scarlet fever during the past nine years, the assertion that the supposed increase of scarlet fever mortality is due to the effect of the Education Act of 1870 naturally falls to the ground, and for present purposes it is hardly necessary to discuss the causation of the decline in the death-rate from scarlet fever in England and Wales during the past nine years. Most of the other principal zymotic diseases show a similar decline of fatality, and afford the strongest evidence of improving sanitary condition; and without attempting directly to attribute this result to the Education Act, we may safely claim that Act as a most powerful ally in the struggle for improved public health. Let us resolutely, therefore, beware of any sinister attempt to discredit that Act on account of the administrative difficulties that must inevitably arise from unrestricted school attendance at epidemic periods.

WOMEN AT THE INTERNATIONAL CONGRESS!

As might have been expected, the determination to exclude women from the scientific meetings of the forthcoming Congress has led to hostile criticism abroad. The following semi-satirical comments appear editorially in *Le Progrès Médical* of last week:—

"Decidedly our English *confrères* are not very gallant, nor also very liberal. We can understand their not being upholders of the practice of medicine by women, and we ourselves have plainly avowed that we did not believe in a general way that this was a career for them. But, when a woman at her own risk and peril, for motives of which she is the sole judge, has thought it her duty to follow this profession, when she has gained—on like conditions to man—the title and diploma of doctor, what reasons can be advanced for refusing her the rights and privileges attached to this title and diploma? Doubtless the honourable organisers of the future International Congress of London have good ones, since by a majority of 27 votes to 19 they have closed the doors of the Congress to women doctors. They must certainly have excellent reasons, since they have extended this ostracism even to those who have already taken part in

other International Congresses. But our penetration cannot divine these reasons. Do they fear that the reputed loquacity of these ladies would cause the Congress to waste too much time? Does past experience confirm this dread, and sanction these precautions? Alas! if they wanted to exclude babblers, those inexhaustible debaters who only speak to say nothing, they must have recourse to more radical measures, and perchance the rigors of a new rule would frequently fall upon the bearded orators.

"In France—the *salic land*—we are less timid; the *Société d'Anthropologie* cordially admits women among its members, and does not bind them to silence. The English Committee of the International Congress of London, which Her Majesty the Queen of England and Empress of India has deigned to take under her high patronage, should have been able, without derogation, to show more courtesy towards the sex to which their sovereign belongs."

We have reproduced the above in its entirety, because it conveys pretty well the idea which probably prevails abroad upon the subject; but without wishing to argue the point, we would venture to point out that in England we are not accustomed to see female doctors at our medical societies yet, and—it may be the fault of our climate, or our insularity, or our conservatism—we have no desire to make what, to many of us, would be a most undesirable innovation, tending to limit free and open discussion.

THE STUDY OF OPHTHALMOLOGY AND ITS BEARINGS.

PROFESSOR HIRSCHBERG'S *Centralblatt für Augenheilkunde* for the present year opens with an address on the above subject. After a succinct but telling sketch of the history of Ophthalmology, the author goes on to say:—"Recent and more exact methods of research have placed it beyond doubt that the condition of the eyes presents us with the best clue to an early and certain diagnosis of various affections of important organs, such as the kidneys and the nervous centres, or of the whole system, as in lues and leucæmia. There being now open to us a direct view of the interior of the eye, we are enabled to recognise the existence of diffuse nephritis in cases where, from the slow development of the disease, neither the patient nor the physician suspected the presence of so grave a disorder. In many cases of military tuberculosis, where the indistinctness of the symptoms leaves us in doubt, this is cleared up by the discovery of tubercles in the choroid. Just as the multiplier, as von Graefe has it, reveals the presence of the very weakest electrical current, the optic nerve, passing as it does through the unyielding scleral aperture, shows by the serous engorgement and the oedema of the papilla unmistakably the existence of increased intracranial pressure, owing, for the most part, to the growth of neoplasms within the cavity of the cranium. The geometrical arrangement of the sentient retinal elements, the cones and rods, enables very limited defects of the field of vision to be exactly defined—defects which to the experienced observer foreshadow, months and even years before, the advent of progressive paralysis. The observation of anomalies in the action of ocular muscles is frequently the first means of detecting the presence of a substantive affection of nerves. The mathematical definition of the functions of the visual organ—viz., distinctness of vision and accommodation, the latter, depending almost entirely on the age of life—reveals the very smallest deficiencies; whereas similar anomalies in other domains—as, for example, in the cutaneous or muscular sensibility—are far from being able to be determined with equal accuracy. From these few instances it will be admitted that the study of our modern ophthalmology, quite apart from its practical bearings, is one of very great pedagogic value to the student of medicine, and is well entitled to the place assigned to it in the examination for the licence to practise. As to its practical merits—its

degree, that is, of therapeutic efficiency—every unprejudiced critic will admit that within the last thirty years notable progress has been made. The local treatment of severe conjunctival affections with caustics; the energetic employment of mydriatics in iritis and even keratitis, the administration of the myotic alkaloids, the mercurial treatment of specific affections of the fundus—all this has undoubtedly contributed to an improvement in the statistics of loss of sight. The operation for cataract has, by virtue of improved diagnosis and encheiresis, come to rank among the most successful performances in surgery. Glaucoma, absolutely incurable before, has, through von Graefe's immortal discovery of the powers of iridectomy, in the overwhelming majority of the cases, become curable, and altogether the scope of that operation, itself greatly simplified, has been vastly enlarged. It must, of course, not be thought that in all the cases which are theoretically curable a cure is actually achieved. The number of the blind is still very large in all civilised countries—with us, e.g., fully 1 in 1000; that is to say, there were in 1871 no less than 22,978 persons in Prussia entirely blind. From the exact statistics of the causes we infer that, according to the present potentialities of the healing art, almost 30 per cent. of the cases might have been rescued from their fate. The principal causes why they were not must be sought in the miserable circumstances of life of large masses of the people, and, above all, in the ignorance of a still greater number, in their predilection for quackery, or their supineness in seeking proper medical assistance. Hence, a vast and fruitful field for exertion lies open before the ophthalmological student."

HEALTH OF THE METROPOLITAN POLICE.

THE report of the Chief Medical Officer of Police, Mr. Timothy Holmes, for the year 1879, shows, among a strength of 10,678, 6489 cases of sickness and 59 deaths. The average number of men on the sick list was 286·7. The total number of men injured was 661, of whom 462 were injured "on duty," and 199 "not on duty." In addition, 149 men suffered from sore feet. The "chief diseases of exposure" were rheumatism (chronic and muscular), coryza, bronchitis, and tonsillitis; and from these ailments 3033 of the men suffered, the larger number being affected with coryza. "Twenty-two men," the report states, "were suspended on account of venereal disease during the year. It has been recently found necessary to send some cases of venereal disease to the Lock Hospital for treatment, on account of the want of any proper place for the treatment of young men affected with the severer forms of venereal disease, when living in stations or section houses. It is stipulated that all such men are to be seen by the chief surgeon on their discharge from hospital, in order that those who are affected with constitutional disease, or who from any other cause are judged unfit for the service, may be reported unfit. It is hoped that the necessity for sending such cases to hospital may not often arise. Though apparently unavoidable under our present system of medical attendance, it certainly looks like a provision for obviating the inconveniences which a man has brought on himself by the breach of police regulations, and to some extent neutralises the regulations whereby such men are struck off pay while unfit for duty. It is only, therefore, in the case of men who can neither be sent home nor treated with convenience in the station that a reference to the Lock Hospital should be made." Notwithstanding the liability of the men, in the pursuit of their duties, to incidental exposure to the contagion of small-pox, only 5 cases occurred in the force—an immunity due to the care given to revaccination. Of the causes of death, "consumption and 'disease of the lungs'" stand first in order of frequency, "bronchitis and pleurisy"

and "bronchitis" second and third. Of the causes of resignation and invaliding from ill-health (the "debility" of age and long service being put aside), "rheumatism, rheumatic gout, and sciatica" come first in order, "consumption and disease of the lungs" second, and "bronchitis" third. Of the duration of cases of sickness, 3130 did not exceed a week.

SIR THOMAS D. ACLAND ON HOSPITAL NURSING.

SIR THOMAS ACLAND, in his capacity of president of the Exeter Hospital, has been giving expression to his views on hospital nursing, observing that good nursing was as necessary as good treatment. He said three things were necessary—first, that medical orders be implicitly obeyed; secondly, that nurses should be trained and educated for their duty; thirdly, that there should be cordial co-operation between medical officers and the person or persons selecting and allocating the nurses. We heartily agree with Sir Thomas in these points. Sir Thomas, rebutting statements in the public press as to the element of religious controversy in this nursing question, said "deliberately, after weeks, nay, several months, of most earnest investigation, that currency had been given to most unjustifiable insinuations about the endeavours to introduce sisterhoods, to set nurses up to judge for themselves, and to put the interest of nurses before that of patients." We are not quite so clear that Sir Thomas is right here. He must be a bold man who denies, in the face of facts everywhere to be noticed, that there is a desire to introduce sisterhoods into hospitals, and many signs of an attempt to turn hospitals into ecclesiastical battle-fields—an attempt which cannot be too closely watched or too stoutly resisted.

THE ORDER OF ST. KATHERINE.

THE Queen has been graciously pleased to confer the Order of St. Katherine on one of the nurses at the Royal Victoria Hospital, Netley, and on the recommendation of Sir William Muir and Lady Superintendent Mrs. Deebles, Sister Elizabeth Wheldon has been selected for the honour. The order carries with it a pension of £50 per annum for a limited period, with an embroidered badge worn on the left arm. Sister Wheldon, in addition to long and good service at Netley, was one of the nurses chosen to accompany Mrs. Deebles to South Africa for work in the military hospitals during the Zulu war, and was commended for her zeal and efficiency in nursing and care of the sick and wounded in that campaign.

THE HOMŒOPATHIC CONGRESS.

WHEN every other body of men is having its Congress it would be hard if the Homœopaths were not to have theirs. Accordingly they have been meeting in Leeds, and have been trying to take a hopeful view of their position in the world. To do them justice we must say that the principal speakers spoke with a modesty and a certain vagueness which contrast favourably with the old and intolerant style of the master. The principal object of the President, Dr. Yeldham, in his address, was to magnify the element of certainty in medicine. This is a sentiment so proper that we can all accept it. But the question is, What is certain? The homœopathic doctrine has been so roughly handled lately by leading homœopaths, that we must consider it, to say the least, very uncertain. We have been lately told by the leading homœopathist in London that the principle of cure is sometimes *similia similibus*, and sometimes *contraria contrariis*, whereas the master said that no future experience would qualify the principle of *similia* as the one and only principle of cure. Recent homœo-

pathic practice raises still stronger doubts about the certainty of the other thing that the master insisted on as established—viz., the virtue of infinitesimal doses. Every now and again good, simple homœopaths, of which a few still survive, are shocked by the rebellion of unworthy disciples. Formerly homœopathy had only to contend with the disadvantage of divorce from scientific medicine; now it has to bear the fate of a divided house. At the dinner in the evening Dr. Yeldham tried to speak comfortably to his brethren on the subject of the slow progress of homœopathy. He thought great reforms were always slow; but considering the reasonableness of the age, and the fast rate at which truth and falsehood are exposed, it is certainly becoming a serious argument against homœopathy that eighty years after its promulgation it is as much without scientific recognition as it was two generations back. About the same time that homœopathy was announced Jenner announced the efficacy of vaccination. Let anybody contrast the fate of the two announcements: the one accepted by every civilised country, and by every medical school in the world: the other, without recognition in any European University, even in Germany, the land of its origin.

QUEEN'S COLLEGE, GALWAY.

THE report of the President of this College for the Session 1879–80 proves that its prospects are encouraging, the students attending lectures during that period having amounted to 180, or 13 in excess of those entered in the previous session. In order to estimate justly the condition and progress of the College from the number of students on the rolls, it must not be forgotten that daily attendance is rigidly enforced in all the departments of the Queen's Colleges. In the Queen's College, Galway, besides the daily roll-call, class examinations are frequently held; for example, in the class of Anatomical Demonstrations a daily examination is held, and in Physiology once a week, and no credit is given for attendance when deficient preparation for lecture or deficient study of the subject is shown by the student. So that the class certificate not merely proves the payment of a fee, and the entry of a name on the class-roll, but is a guarantee of continuous study of the subject on the part of the student during the entire session. It appears that there is an urgent necessity for enlarged accommodation in the Anatomical Department of the Medical School, the Lecture Theatre and the Practical Room being inconveniently crowded.

WICKERSHEIMER'S METHOD OF PRESERVING ANATOMICAL PREPARATIONS AND WHOLE BODIES.

DR. HOTZ states in a recent number of the *Chicago Medical Journal* that Dr. Wickersheimer, prosector in the Anatomical Institute at the University of Berlin, has invented a new preserving fluid, by means of which it is possible to preserve any organic bodies, either plants or animals, so perfectly that they retain their original form, colour, and texture. The inventor at first secured a patent for his invention, but in the interest of science he relinquished it. The fluid in question is thus prepared: 100 grains of alum, 25 grains of cooking salt, 12 grains of saltpetre, 60 grains of potash, and 10 grains of arsenious acid, are dissolved in 3000 parts of boiling water. The solution is cooled and filtered. To every 10 litres of this neutral colourless and odourless fluid there are added 4 litres of glycerine and 1 litre of methyl-alcohol. For dry preservation the preparations are immersed in the fluid from six to twelve days, according to their size, and then dried in the air. Organs like the lungs and intestines are filled with the fluid before immersion, and blown up before drying. Small animals and portions of bodies which are to be preserved in their natural colours are

simply kept immersed in the fluid. For embalming, the body is injected and laid in the fluid for several days. It is then taken out, rubbed off, and dried and wrapped in linen or oil-cloth saturated with the fluid, and encased in air-tight receptacles. If bodies are to be temporarily embalmed for scientific purposes, the injection of $1\frac{1}{2}$ litres (for children) to 5 litres (for adults) is sufficient. Even after years the cut surface of the muscles shows the appearance of those of a fresh corpse. Bodies treated in this way have not the least odour.

IRISH UNIVERSITY EDUCATION.

AT the approaching meeting of Convocation of the Queen's University in Ireland, a motion will be brought forward to the effect that without reference to demands for endowed sectarian universities or colleges, Dublin University should occupy in relation to any university the same position as the Queen's University. Also, that existing non-sectarian colleges—namely, Trinity College, Dublin, and the three Queen's Colleges—should be affiliated colleges in a non-sectarian teaching university; that by additional endowments they should have similar advantages as regards professorships, residences, fellowships, and exhibitions; and that a deputation be appointed to submit the views of Convocation to the Prime Minister and Chief Secretary for Ireland.

THE MIGRATION OF OVULES.

MM. DUVAL and WIET have investigated the mechanism by which the ovules pass from the ovary to the Fallopian tube, in order to ascertain whether ciliary action does not play a part in the phenomenon. They have found that in female frogs, during the sexual period, the peritoneum is covered by an epithelium furnished with vibratile cilia, in active movement. The cilia are absent at other times, and in the male frog. A similar epithelium was found on the peritoneum of cats during the rutting period. M. Sinéty has found vibratile cilia on tumours removed from the pelvis of women immediately after the catamenial period; and therefore it may be assumed that a similar mechanism is also in operation in the human species.

"THE PEOPLE'S DISPENSARY."

THERE is great danger of the people being victimised by dispensaries of one sort or another. We put them on their guard. Wherever medicine and attendance are offered at very low charges let them consider whether they are likely to get anything worth having. At Liverpool police-court the stipendiary magistrate has just committed for trial John Oldenham, of the "People's Dispensary," for falsely pretending to be a duly qualified medical practitioner, and for giving false certificates of death. It was urged for the defence that the defendant acted under a qualified practitioner; but the practitioner in question denied the statement.

CYSTICERCAL EMBRYOS.

M. POINCARÉ lately described some curious parasites in beef, and he has recently found similar organisms accompanying cysticerci in measly pork. They are extremely numerous, and their number is in inverse proportion to the cysticerci, which suggests that the two are really successive stages of the same individuals. They are of an ovoid form, and consist of a sac containing only a mass of granular protoplasm. This sac is capable of spontaneous movements, by which its form may be considerably modified. Most of them are furnished with vibratile cilia, which are more numerous and longer towards the extremities. Some were free, others were contained within muscular fibres. Regarding them as phases of development of cysticerci, M. Poincaré believes that they

may also give rise to tapeworms, but has not yet proved this by experiment.

INQUIRY AT CORK FEVER HOSPITAL.

A PUBLIC INQUIRY has just closed in Cork Fever Hospital in reference to a case of scarlet fever in a pay ward of the hospital, in the treatment of which the use of a small dose of pilocarpin subcutaneously was adopted. The case appears to be exciting considerable interest amongst the profession in Ireland. We reserve a fuller notice of the case, which we have received from our Cork correspondent, until the decision of the committee is made known, and the statements and explanations of the medical men concerned shall be in our possession.

CABUL.

PRIOR to the complete evacuation of Cabul by Sir Donald Stewart's army, the sick of the force, European and native, were encamped in the Balla Hissar on the 26th July, and were inspected by the General the same evening. The convoy, which consisted of 414 Europeans, 445 Sepoys, and 129 native followers, started for India on the 27th, and was under the command of Major Kingsley, 67th Regt. Surgeons Kirkpatrick and Langridge accompanied the party.

CONSIDERABLE difference of opinion appears to exist in the minds of those interested in the prosperity of the Hastings and St. Leonards Infirmary as to the desirability of changing the site of the building. A general committee appointed by the governors to consider the report of the Site Committee had endorsed the recommendation by the latter body that negotiations should be entered into for the purchase of what would seem to be an eligible plot of ground called St. John's Villa, the cost of which was stated to be £10,000. At the half-yearly meeting of the governors of the infirmary, held on the 7th inst., a resolution was carried in harmony with this recommendation.

AMONGST several liberal legacies to medical and other charities, Mrs. Sally Halls Bradshaw, the widow of Dr. William Woods Bradshaw, F.R.C.S. Eng., late Mayor of Reading, has bequeathed to the Royal College of Physicians the sum of £1000, and a similar amount to the Royal College of Surgeons of England, both described as "for a special purpose;" to the Royal Berkshire Hospital, £1000; to the Winchester County Hospital, £1000; to the Westminster Hospital, £1000; to the Reading Dispensary, £500; to the Royal Hospital for Incurables, £1000. The will is sworn under £35,000.

DR. G. E. NICHOLAS, of Church-row, Wandsworth, whose second son was unfortunately drowned at Ipswich on the 28th ult., was, we learn, last week nearly experiencing another bereavement of a similar kind. Dr. Nicholas's third daughter fell into the river Wandle, which runs at the bottom of his garden, and but for the generous bravery of his next-door neighbour, Mr. Cooke, chemist, who unhesitatingly jumped into the stream, and succeeded in bringing her to the shore, the young lady must have suffered the melancholy fate of her brother.

FRANCESCO RIZZOLI, Professor of Surgery at the University of Bologna, who died recently, has bequeathed his vast wealth, estimated at nearly 6,000,000 francs, to the Municipality of Bologna, with the stipulation that it should be devoted to the completion and maintenance of the Model Orthopædic Hospital on his estate at San Michele, in Bosco, an institution on which he had, during his lifetime, expended a sum of 2,000,000 francs.

WE regret to learn that cholera, in a severe form, has broken out at Fort Abizai, near Peshawur. The native regiment in garrison there reported thirty cases the second week in August. We trust the epidemic will be confined to the Fort, and not spread generally in the Peshawur Valley, through which our troops are now marching on their return from Cabul to India.

WE have been asked to announce that the engagement of foreign medical officers for the Netherland Indian Military Service is discontinued.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Jarrow (estimated population 22,500.) Mr. John Spears' report on the health of Jarrow during the year 1879 contains, perhaps, the most important and assuring information which has yet been published by a medical officer of health on the efficacy of the action which may be taken for preventing the spread of disease by a sanitary authority who have obtained power for the compulsory notification of infectious diseases in their district, even when they do not possess a hospital. This is the case with the Jarrow sanitary authority. They possess a local Act of Parliament giving them exceptional powers for securing information regarding the existence of, and for dealing with, infectious sickness, but, curiously (putting the cart before the horse, so to speak), have no infectious-disease hospital. Nevertheless, Mr. Spears shows that the power for the compulsory notification of disease may be turned to excellent account, though what ought to be a primary condition of granting such power is wanting. Mr. Spears' observations on this subject and on a remarkable outbreak of true typhus which occurred in Jarrow last year, we shall follow in great part textually.

Compulsory registration of disease, he remarks, is a measure which of necessity must form the groundwork of all satisfactory provision for the stamping out of such disease, and has been in operation in Jarrow during the year. "In its practical application it has been found, it may truly be said, perfect, and has left really nothing to be desired. If one tried hard to find fault one might say that in a few cases the certificates have not come in at quite so early a date in the course of the case reported upon as was desirable; but on the other hand, much more frequently it has happened that I have received unofficial notice of doubtful cases before a certain diagnosis in regard to them could be arrived at. In one solitary case only, and I have watched for such occurrences, could the suspicion arise that the patient's friends had not sent for medical aid through fear of the case being reported, and in this one case it was merely a suspicion, denied by the parties concerned. So far, again, from this provision bringing the medical officer of health, and the medical practitioners into conflict, as had been predicted by some, it has assisted in the formation of a close and pleasant intimacy between us, and a mutual confidence, which was freely illustrated during the year, when, on the occurrence of many cases presenting unusual and somewhat contradictory clinical features, I was permitted without a single objection to visit such cases, and take clinical observations, often twice a day, and for days continuously. The medical practitioners of the town are in one accord as to the efficacy and practicability of the measure, and most of them are now its warm supporters, whilst from private individuals I have not heard one single objection, unless a slight demur, only expressed privately, to an unusually late visit I paid on one occasion to a house for the first time, could be called such. The smoothness of its working, and the practicability of this measure are, in short, established by the experience of Jarrow; provided, as has been pointed out to me by my professional brethren, the medical officer of health is not engaged in private practice, and is reasonably conciliatory

in his dealings. Then, as to its usefulness. On this point I can speak with greatest decision in respect of the behaviour of a recent typhus fever outbreak. It may be said that typhoid fever has diminished, that the epidemic of scarlet fever, when we came to be informed of every case as it arose, soon disappeared, whilst in neighbouring districts it continued almost unabated; but this I pass over, it may be due to other causes, while the experience with regard to typhus fever is, I take it, decisive."

The infection of this last-named disease had existed in the district, in no inconsiderable degree, throughout the year, and yet there was nothing approaching an epidemic outburst. "Could we," writes Mr. Spears, "have in a district where typhus fever has not appeared for years, and amongst a low-class, closely packed, often under-fed population, always throughout a whole year, five or six different centres of typhus infection, and yet no outburst, unless it were for the prompt precautionary measures that were applied? It is at least most unlikely. In all human probability the infection would have assumed, under such conditions, its usual form of an ill-defined epidemic wave, difficult to trace in its individual progress, and not have remained, as I shall presently show it did, a mere dribbling stream, kept within a very narrow and always perfectly obvious channel. Moreover, the efficacy of prompt precautionary measures was demonstrated in numerous individual cases almost with the accuracy of a scientific experiment. I will mention one instance of many. For seven weeks the typhus infection existed in the house of one J—, in Shakespeare-street. With one exception, the family all suffered, the sufferers being at last removed by the parish authorities. During this time all but one neighbour was rigidly excluded. That neighbour, and that one only, took the disease, and subsequently her husband and all her husband's family suffered.¹ Had it not been for our strict supervision (I visited the house myself almost always twice a day, and the inspector only a little less often) many neighbours would have been constantly passing to and fro, each with a more than equal chance, for other precautions would have been likewise neglected, of infection. Such was throughout the experience. When persons insisted on seeing a sick or dying relative, or upon attending a funeral party in an infected house, they caught the disease; when a lover visited surreptitiously his sick mistress (four such instances occurred) he paid a like penalty; when a neighbour was allowed to nurse a patient, or lay out a corpse, she suffered; whenever such and similar indiscretions were allowed, and it was very difficult, sometimes impossible, to prevent them, the disease spread; when they were prevented it disappeared. In short, throughout, it may be said, we retained an effectual grasp upon the disease; when even a finger was relaxed, we could see, as it were by its effects, the infection oozing away; when the grasp tightened, it was stayed.

"The question will here naturally suggest itself to a stranger, and it may be noticed parenthetically, why was not a hospital provided, and the dozen or so sufferers, since you never appear to have had more than that number at one time, removed, and all this trouble and waste of life put a stop to? The question may well be asked.

"But could we have done what we did, and, without actually stamping it out (we had not the necessary machinery for that), have kept the disease so completely under control, without our system of registration of disease? Assuredly, no! The disease would almost certainly have become epidemic; we should only have been dealing with one centre of infection, whilst others unknown to us were arising. And for this reason I think I may justly say that if our Private Act were destroyed at this moment the benefits that have already accrued from it are such that the ratepayers would have been more than repaid the cost of obtaining and administering it.

"Typhus fever, a disease that for years had been absent from this district, made its appearance in February of the year under report. Its origin is left in uncertainty, although to discover it no pains were spared. The grandfather of the first infected family had lately come to the house from Sunderland, from a part where the disease had to a moderate extent prevailed, and this was the most likely source of the contagion that could be suggested. This part of the investigation was rendered somewhat more difficult by the fact that, especially in the early cases, the clinical features of the

¹ One of the sufferers, however, went to stay a night at the house of a friend, owing to a quarrel at home, before complete recovery, and infected persons there.

disease were so equivocal that at first it was looked upon as typhoid fever, but this feature of the epidemic, together with other technical points of much interest, may more properly be left for a scientific paper. What most concerns the sanitary authority to know is that the disease spread, it could clearly and unmistakably be proved, in almost every case, by contagion from person to person, or, in a few cases only, by infected clothing; and, also, that ill-ventilated and crowded houses suffered far beyond all proportion of what may be termed the balance of probability of their infection. Persons living in crowded rooms appear to have been peculiarly susceptible to the reception of the fever poison; and, when the disease appeared in a crowded house, not only did all, or nearly all, the inmates invariably suffer, but such houses formed centres of infection from which it was almost impossible to prevent the disease from spreading. Both these facts, of so much significance to the authority—the mode of spread of this disease, and the peculiar facility which overcrowded dwellings offer to its propagation—constitute no new experience, but have been observed before in nearly every epidemic of typhus fever. Still, they are, as I have said, of so much practical importance, that it is well to insist upon them."

These points are brought out in a table annexed to the report, in the form of a chronological diagram, and from which one example may be given. The disease started in an overcrowded house in High-street, nine persons in this house suffered, and from it seven others, or twenty-seven persons, were directly infected. From only one of these houses did the disease spread to any extent, and this was likewise an overcrowded house situated in Pearson-place, in which most of the family suffered; from it certainly nine, probably ten, families were infected, and eighteen persons. One only of these houses was overcrowded, and here again all the family suffered, and the disease spread. Such throughout was the experience, as the table shows.

"The information conveyed in this diagram," Dr. Spears observes, "may be looked upon as reliable. Where any reasonable doubt existed as to the source of the infection, such cases have not, of course, been included; but, as I have said, we had great and unusual facilities for watching the progress of the disease, and, indeed, we often knew before the disease broke out in a family that it was likely to appear there, and the source whence it would come. The sanitary authority had, in fact, provided us with most effectual means, by the system of compulsory registration of disease, of watching the ravages of infection, but unfortunately they had not provided us with the means of staying its progress. I must confess I sometimes felt in the position of an observer, watching the carrying out of painful pathological experiments, as useless as preventable, on living animals. We were, as the table will show, generally successful as regards most of the centres of infection, in stopping the progress of the disease by such precautionary measures as we could enforce in the sufferers' houses, and certainly there was no relaxation in our efforts in that direction; but the one thing needed to put an effectual end to all the disease and death and misery that we were coolly watching—hospital accommodation—the sanitary authority could not, or would not, provide. That question was still, as it had been for five years, *under consideration*."

THE BELFAST WORKHOUSE.

Dr. McCabe's report on the State of the Belfast Workhouse has been issued as a Parliamentary paper. The Local Government Board (Ireland), when formed, prided itself in following the administrative example in sanitary matters of its bigger brother, the English Board. It would appear that the Irish Board, when in its larval state of existence, had qualified itself much as the English Board had done. Neither had seen anything incongruous in undertaking the public health administration of a kingdom, after having proved itself unqualified to manage the somewhat simpler duty of properly supervising the sanitary administration of a workhouse. The Belfast workhouse, according to Dr. McCabe's report, shows that Local Government officials in Ireland have quite equalled the Local Government officials here in the sanitary mal-administration of workhouses, and no doubt they feel highly gratified in having emulated so successfully in this branch of their administrative duties their English brother. The Belfast workhouse would have been worthy of a place in THE LANCET'S first report on Workhouses.

SANITARY CONDITION OF CLONAKILTY.

This town appears to be in a bad condition in reference to sanitary matters and the absence of a proper supply of water. The Town Commissioners last week unanimously adopted a resolution that a memorial should be forwarded to the Local Government Board, requesting that the sanitary authority be transferred from the Board of Guardians to the Commissioners, as the Guardians were neglecting their duties.

At a recent meeting of the Hackney Board of Guardians some amusement was excited by a drug account. The clerk was called upon to read it, but he asked to be exempted from the task, on the ground that whilst the list kept to Latin, he could manage to decipher it, but when it went off, as was the case at intervals, into his native tongue, he was completely at fault. Further amusement was caused by Dr. Millar discovering in the list an item of a gallon of brandy sandwiched between 28lb. of zinc ointment and some tincture of squills.

A case of proceedings for adulteration is reported from the Wolverhampton police-court, in which the stipendiary magistrate decided that it must be dismissed, because the county analyst, certifying to the quality of the asserted adulterated article, coffee, had described it as consisting "practically" of chicory. It was objected to this certificate that it did not state the quantity of chicory, and the magistrate held that it was not sufficient evidence of adulteration.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

35th week.—Notwithstanding the recent high temperature, the rate of urban mortality and of diarrhoea fatality showed a slight decline in the week ending Sept. 4th. In twenty of the largest English towns, estimated to contain in the middle of this year seven and a half millions of persons, or nearly one-third of the entire population of England and Wales, 4984 births and 3534 deaths were registered. The births were 201 below, whilst the deaths exceeded by 259, the average weekly numbers during 1879. The deaths showed a decline of 71 from the steadily increasing numbers in recent weeks, and were equal to an annual rate of 24·6 per 1000; in the nine preceding weeks the rate rose from 18·9 to 25·1. The lowest death-rates in the twenty towns in the week under notice were 19·4 in Oldham, 19·5 in Plymouth, 20·8 in London, and 21·7 in Bristol. The rates in the other towns ranged upwards to 34·4 in Liverpool, 34·6 in Nottingham, 35·1 in Salford, 35·3 in Norwich, 37·6 in Sunderland, and 38·2 in Leicester.

The deaths referred to the seven principal zymotic diseases in the twenty towns, which had steadily increased in the twelve preceding weeks (under the influence of summer diarrhoea) from 406 to 1239, declined to 1120 in the week ending Sept. 4th. Of these, 853 resulted from diarrhoea, 93 from scarlet fever, 70 from whooping-cough, and 51 from fever, principally enteric. The annual death-rate from these seven diseases averaged 7·8 per 1000 in the twenty towns, and ranged upwards from 4·2 and 4·9 in Plymouth and Brighton, to 17·4 and 19·3 in Salford and Leicester. Scarlet fever showed the largest proportional fatality in Norwich and Sunderland, and diphtheria caused 2 deaths both in Portsmouth and Birmingham, and 10 in London. The deaths referred to enteric fever showed a marked excess in Portsmouth and Plymouth. Small-pox caused 5 more deaths in London, but not one in any of the nineteen large provincial towns.

The fatal cases of diarrhoea in the twenty towns, which had steadily increased in the eleven preceding weeks from 51 to 958, declined to 853. The annual death-rate from diarrhoea averaged 5·9 per 1000 in the twenty towns; it did not exceed 3·3 in London, whereas it was equal to 8·5 in the nineteen provincial towns. Among the twenty towns the death-rate from diarrhoea in the week ending September 4th ranged from 2·1 and 2·9 in Plymouth and Brighton to 13·9 in Hull, 14·1 in Salford, and 18·1 in Leicester.

The deaths referred to diseases of the respiratory organs in London, which had been 167 and 124 in the two preceding weeks, rose again to 152, and exceeded the corrected weekly average by 6; these included 79 from bronchitis and 43 from pneumonia. The annual death-rate from diseases of

this class was equal to 2·2 in London and to 3·5 in Liverpool.

36th week.—The recent high temperature caused an increase in the rate of urban mortality, which was higher last week than it has been since the middle of February last. In twenty of the largest English towns, 4962 births and 3643 deaths were registered last week. The births were 223 below, whereas the deaths exceeded by no less than 368, the average weekly numbers during 1879. The deaths showed an increase of 109 upon those returned in the previous week, and were equal to an annual rate of 25·4 per 1000, against 25·1 and 24·6 in the two preceding weeks. During the ten weeks ending the 11th inst. the death-rate in these twenty towns averaged 23·1 per 1000, against 24·7 and 18·1 in the corresponding periods of 1878 and 1879. The lowest death-rates in the twenty towns last week were 19·6 in Bristol, 19·8 in London, 23·5 in Birmingham, and 23·7 in Plymouth. The rates in the other towns ranged upwards to 35·8 in Sunderland, 38·5 in Wolverhampton, 38·6 in Liverpool, 38·6 in Leicester, and the highest rate was 39·0 in Salford. The zymotic death-rate (mainly the result of infantile diarrhoea), showed a marked excess in each of the five last-mentioned towns.

The deaths referred to the seven principal zymotic diseases in the twenty towns, which had been 1239 and 1120 in the two preceding weeks, rose again to 1190 last week. Of these, 917 resulted from diarrhoea, 111 from scarlet fever, and 67 from other forms of fever, principally enteric or typhoid. The annual death-rate from these seven diseases averaged 8·3 per 1000 in the twenty towns, and ranged upwards from 4·8 and 6·4 in London and Bristol, to 21·7 and 22·7 in Leicester and Salford. Scarlet fever, the deaths from which were more numerous than in recent weeks, showed the largest proportional fatality in Norwich, Salford, and Sunderland. The deaths referred to fever, principally enteric, in the twenty towns, which had been 40, 49, and 51 in the three preceding weeks, further rose to 67 last week, a higher number than in any previous week this year; only 18 occurred in London, whereas 49 were returned in the nineteen provincial towns, having an aggregate population only slightly larger than that of the metropolis. The fatality of fever showed the largest proportional excess last week in Plymouth, Portsmouth, and Sheffield. Small-pox caused 5 more deaths in London, but not one in any of the nineteen large provincial towns. The number of small-pox patients in the Metropolitan Asylum Hospitals have steadily declined from 200 to 104 during the eight weeks ending last Saturday; 13 new cases of small-pox were admitted to these hospitals during last week, against 26 and 7 in the two previous weeks. The Highgate Small-Pox Hospital contained 9 patients on Saturday last.

The fatal cases of diarrhoea in the twenty towns, which had been 958 and 853 in the two previous weeks, rose again to 917 last week, and were equal to an annual rate of 6·4 per 1000; in London it did not exceed 3·2, while it averaged 9·4 in the nineteen provincial towns. Among the twenty towns the death-rate from diarrhoea last week ranged from 3·2 and 3·9 in London and Bristol, to 18·5 and 19·7 in Salford and Leicester. During the four weeks ending last Saturday diarrhoea fatality in Leicester was unprecedentedly great, even for that town, and was equal to an annual rate of 18·9 per 1000.

The deaths referred to diseases of the respiratory organs in London, which had been 124 and 152 in the two preceding weeks, declined again to 124 last week, and were 18 below the corrected weekly average; 68 resulted from bronchitis, and 38 from pneumonia. The annual death-rate from lung diseases was equal to 1·8 per 1000 in London, to 5·7 in Liverpool, and 2·8 in Salford.

HEALTH OF SCOTCH TOWNS.

In eight of the largest Scotch towns, having an estimated population of rather more than a million and a quarter persons, the annual death-rate last week averaged 18·2 per 1000, against 18·4 and 19·3 in the two preceding weeks; this rate was no less than 7·2 per 1000 below the average rate in the twenty large English towns. The rates in the eight Scotch towns ranged from 13·4 and 13·6 in Dundee and Aberdeen, to 23·3 and 33·8 in Paisley and Leith. The fatal cases of the seven principal zymotic diseases in the eight towns was 129, against 123 and 130 in the two preceding weeks; they included 63 from diarrhoea, 18 from scarlet fever, 16 from diphtheria, 15 from fever, 13 from whooping-cough, 4 from measles, and not one from small-

pox. The annual death-rate from those seven diseases averaged 5·2 per 1000 in the eight towns, against 8·3 in the large English towns; the excess in the English towns was mainly due to the far greater fatality of infantile diarrhoea. The zymotic death-rate in the Scotch towns ranged last week from 0·0 and 3·4 in Perth and Dundee, to 6·8 and 8·8 in Edinburgh and Leith. The fatal cases of diarrhoea in the eight towns, which had been 63 and 65 in the two previous weeks, were again 63 last week, and were equal to an annual rate of but 2·5 per 1000, while in the twenty English towns the diarrhoea death-rate averaged no less than 6·4. The largest proportional fatality of diarrhoea in the Scotch towns occurred in Aberdeen, where however the rate did not exceed 3·5 per 1000. It is stated that for the purpose of these Scotch weekly returns deaths from "enteritis and other bowel diseases are grouped under the heading diarrhoea"; this deliberate misclassification is to be regretted. It is also noted that "croup, laryngismus stridulus, and certain cases of disease of the windpipe" are returned under the heading of diphtheria. Such irregularities of classification detract much from the value of the Scotch weekly returns for comparative purposes. During last week, for instance, 16 fatal cases of diphtheria are reported in the eight Scotch towns, against 15 in the twenty English towns, with a population six times as numerous. If any large proportion of these so-called fatal cases of diphtheria were really due to croup, or laryngismus stridulus, the return conveys a mischievously false impression. The 15 deaths referred to fever showed an increase upon recent weekly numbers, and included 7 in Glasgow, and 4 in Edinburgh. Of the 18 fatal cases of scarlet fever 8 were returned in Edinburgh, 4 in Leith, and 5 in Glasgow. The deaths attributed to acute diseases of the lungs (bronchitis, pneumonia, and pleurisy) were 60 last week in the eight Scotch towns, against 55 and 65 in the two preceding weeks; the annual death-rate from these diseases was equal to 2·4 per 1000 against 1·5 in London.

HEALTH OF DUBLIN.

The death-rate in Dublin continues excessive. The annual death-rate in the city, which had been equal to 37·8 and 35·5 in the two preceding weeks, showed but a slight further decline last week to 34·7. During the first ten weeks of the current quarter the death-rate in the city has averaged no less than 33·6 per 1000, against 21·7 in London, and 18·3 in Edinburgh. The 209 deaths in Dublin last week included 61, or more than 29 per cent., which were referred to the seven principal zymotic diseases, exceeding by one the number in the previous week; 32 resulted from diarrhoea, 8 from scarlet fever, 8 from whooping-cough, 7 from fever, 5 from measles, 1 from diphtheria, and not one from small-pox. The annual death-rate from these seven diseases was equal to 10·1 per 1000 in Dublin, while it did not exceed 4·8 in London, and 6·8 in Edinburgh. The fatal cases of diarrhoea in Dublin, which had been 36 and 29 in the two previous weeks, rose again to 32 last week, and were equal to an annual rate of 5·3 per 1000, against 3·2 in London. The deaths from scarlet fever showed a decline of 7 from those in the previous week, whereas the number of those referred to measles and whooping-cough varied but slightly. The 7 fatal cases of fever exceeded the number returned in any of the six preceding weeks. Infant mortality was greater in Dublin last week than in any previous week this year.

HEALTH MATTERS GENERALLY AT HOME AND ABROAD.

THE METROPOLITAN COMMON LODGING-HOUSES.

The report of the Chief Commissioner of the Metropolitan Police for the year 1879 supplies the following particulars as to the lodging-houses under the supervision of that force, and the occurrence of infectious and contagious diseases in them during the year. At the close of the year there were open within the metropolitan area 1220 registered common lodging-houses, accommodating 24,296 lodgers. The number of cases of infectious and contagious sickness which occurred in them was only 27, as compared with 55 in the previous year—namely, 10 of small-pox, 1 of typhus fever, 2 of scarlet fever, 4 of enteric fever, 1 of typhoid fever, 4 of "fever," and 5 of measles. Twelve cases of itch were also reported.

The deaths taking place in the lodging-houses numbered

74. In every instance an inquest was held, the result showing, as in former years, that the deaths were caused by "privation, exposure, &c." The Chief Commissioner, with regard to cases of sickness requiring removal, remarks on the prompt attention shown by the parish authorities "as heretofore," and observes that "the police had experienced the same kind and courteous attention at the hands of the medical officers as had previously been shown." He expresses also his approval of the systematic and satisfactory way in which the police have maintained their supervision over the houses. It appears that a common lodging-house is in course of erection at Poplar, to provide accommodation for 428 lodgers, and which is being built expressly for the purpose, and will give very superior accommodation, including hot and cold water-supply to the lavatory. No lodging-house has hitherto been constructed or arranged for so large a number of inmates; and none before, it would seem, has sought to emulate in any form the artisan's "model dwellings." The Chief Commissioner anticipates that the new lodging-house will prove a great boon to the working population of Poplar.

BUREAU OF PUBLIC HEALTH IN CANADA.

At the first annual meeting of the newly-elected Medical Council of Ontario, held on July 13th, 1880, Dr. Grant proposed "That, in order to keep pace with the scientific progress of the age, and give greater evidence of an earnest desire to promote sanitary measures, this Council is of opinion that a Central Bureau of Health should be established at the capital under the control of the Federal Government." The motion, along with other resolutions setting forth the importance of public health, was carried unanimously. Thus onward moves the world.

CHOLERA IN RUSSIA.

A short time ago we referred to a reported outbreak of cholera on the Volga, at Saratoff. As the news then reached us it appeared as if a series of cases of accidental poisoning were in question, but fuller information described the malady as having broken out widely among the troops in camp near the town, and afterwards having spread to the inhabitants of the town. Further news describes also a considerable outbreak of choleraic disease among troops encamped in Orel, in Central Russia, as many as 700 soldiers having been struck down with the malady. There the outbreak was assigned to the intense heat of the weather and to the badness of the water in use in the camp. We must wait for clearer information before the nature of this reported cholera can be described and the circumstances which gave rise to it.

According to the annual report of the Commissioner of Police of the Metropolis, the increase of the metropolis during 1879 comprised 21,589 new houses, forming 401 new streets and two new squares, of a total length of 71 miles and 758 yards. This makes the length of new streets added to the metropolis and handed over to the police protection during the last ten years 383 miles and 758 yards.

The *Isle of Man Times* contradicts a rumour that "black fever" has been prevalent in the island, which, our contemporary states, was never in a more healthy condition than it is at present.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE following special notice to candidates as to the payment of fees for the first and second professional examinations for the Fellowship has been issued:—

"All candidates presenting themselves for the first time, whether at the first or at the second Professional Examination for the diploma of Fellow, will be subject to the payment of fees, in accordance with the provisions of the following bye-law of the College, and all candidates who shall hereafter be rejected at either of these examinations will also be subject to the conditions of the said bye-law.

"Every candidate for the diploma of Fellow shall pay the following fees—that is to say, prior to his first and every subsequent admission to the first or Anatomical and Phy-

siological Examination: (a) If a Member, a fee of five guineas, which shall be retained in either case, whether he pass or fail to pass his examination. (b) If not a Member, a fee of ten guineas, which shall be retained if he pass, and of which five guineas shall be returned if he fail to pass his examination. Prior to his first and every subsequent admission to the second Professional Examination—(c) If a Member, a fee of ten guineas over and above all charges for stamps. Such fee shall be retained whether he pass or fail to pass such examination; but the charges for stamps shall be returned if he fail to pass his examination. (d) If not a Member, a fee of twenty guineas over and above all charges for stamps. Such fee and the charges for stamps shall be retained if he pass; but ten guineas, part of such fee and the said charges for stamps, shall be returned if he fail to pass his examination. Provided always that no candidate for the diploma of Fellow shall be required before admission to examination or otherwise to pay altogether more than thirty guineas over and above the charges for stamps, and that the moneys paid by each candidate and retained as aforesaid shall be treated as the fee payable and paid by such candidate on admittance to the diploma of Fellow."

THE SERVICES.

MEDICAL OFFICERS AT KANDAHAR.

The following officers of the Army Medical Department were on duty at Kandahar, and with General Burrows' force prior to the disaster at Khushi Nakhud:—

At Kandahar: Deputy Surgeon-General J. O'Nial, Principal Medical Officer; Surgeon-Major B. T. Giraud in charge 2-7th Fusiliers; Surgeon-Majors J. F. Beattie, W. R. G. Hinds, and Surgeon G. MacNeece, with the Base General Hospital; Surgeon-Major H. Waghorn, and Surgeon J. Findlay, with the Field Hospital; Surgeon J. Macnamara, in charge C-2nd R.A.; Surgeon E. W. Kelsall, in charge 5-11th R.A.

With General Burrows: Surgeon-Major C. H. Harvey, in charge E-B R.H.A. (reported at Kandahar); Surgeon-Major J. D. Edge and Surgeon E. A. H. Rose, with the Field Hospital (missing—not yet reported); Surgeon-Major A. F. Preston, in charge 66th Regiment (reached Kandahar severely wounded).

At Khelat-i-Ghilzai: Surgeon-Major J. W. Jackson, in charge Field Hospital.

Medical officers of the Indian Medical Department:—

At Kandahar: Surgeon-Major J. Arnott, 19th N.I.; Surgeon A. K. Stewart, Poonah Horse; Surgeon R. Mason, and G. H. Earle, Base Native Hospital (Dr. Earle reported to have reached Kandahar); Surgeon E. Tully, Civil Surgeon.

With General Burrows: Surgeon H. Dane, 1st N.I.; Surgeon G. E. E. Burroughs, 3rd Scinde Horse; Surgeon A. F. Strut, 3rd Light Cavalry; Surgeon W. R. Kirtaker, 30th N.I. (Drs. Dane and Burroughs have been reported safe at Kandahar).

At Khelat-i-Ghilzai: Surgeon-Major E. Morton.

MEDICAL OFFICERS FOR THE BOMBAY BRIGADE ORDERED TO AFGHANISTAN.

The following medical officers of the Indian army have been ordered for service with the Bombay Brigade detailed for Afghanistan:—Surgeon-Majors Beatty and Davidson, Surgeons Macrury, Clarkson, Parker, Chanmer, Hatch, Monks, Damania, and Faulkner. Surgeons Ward and Dempsey are ordered from Ruk and Sehwan to Kandahar for duty.

Deputy Surgeon-General R. H. Perkins, Indian Medical Department, has been appointed principal medical officer 1st Division Northern Afghanistan Field Force, *vice* Deputy Surgeon-General H. B. Hassard, invalided to India.

Surgeon Williamson was appointed to the staff of General Sir Frederick Roberts at Cabul prior to the departure of the division for Kandahar, *vice* Surgeon Owen, transferred to the staff of Sir Donald Stewart.

ADMIRALTY.—The following appointments have been made:—Staff-Surgeon R. G. Bird and Surgeon G. J. Fogerty to the *Carysfort*; Surgeon M. O'C. McSwiney to the *Revenge*; Surgeon W. J. Vollatti to the *Rambler*, when

commissioned; Surgeon William Brown to Plymouth Hospital; Surgeon William Pearson, M.D., to the Royal Marine Artillery.

Correspondence.

"Audi alteram partem."

THE IMMEDIATE TREATMENT OF STRICTURE OF THE URETHRA.

To the Editor of THE LANCET.

SIR,—Absence from England prevented my attending the meeting of the British Medical Association at Cambridge, or I should have availed myself of the opportunity of taking part in the discussion on Sir Henry Thompson's paper on stricture, and could have given such testimony in favour of the immediate treatment as would have satisfied the most sceptical of the value of the operation, and of its security and success.

I never have replied to Mr. Teevan's criticisms, and I never intend to do so, simply from the fact that his experience of the operation being limited (as he informed me in a letter some time since) to four cases, I consider he is perfectly incompetent to form any opinion as to the value of the operation or its results. Mr. Wood, however, stated that he had seen several fatal cases, and I therefore, on my return to London, wrote to that gentleman asking for the number and the particulars of the cases he alluded to. Mr. Wood, in his reply, informed me that the deaths, two in number, occurred in the practice of his colleagues at King's College Hospital, and so far as he could remember they were both operated upon by the late Mr. Partridge. In one Mr. Wood could not recollect any particulars, but in the other he remembers that the patient was the subject of albuminous urine, and correctly adds, "This, of course, was hardly a proper case for any operation of the kind."

I therefore venture to affirm that, considering the large number of operations that have been, and continue to be, performed by surgeons at home and abroad, the fact of only two deaths having occurred, one of which, it is quite clear, should never have been operated upon, speaks volumes in favour of the immediate plan and its eminently satisfactory results. In conclusion I may add, that I am as strongly in favour of the operation as I ever was, and that I have this day operated with the most perfect success on an unpromising and difficult case; at the same time I warn those who are deficient in the manipulative skill required for the passage of the dilator to refrain from using an instrument with which they are practically unacquainted.

Very faithfully yours,

Savile-row, Sept. 14th, 1880.

BARNARD HOLT.

"NEW INSTRUMENT FOR CLEFT PALATE."

To the Editor of THE LANCET.

SIR,—Would you favour me with a small space in your journal to make a few remarks concerning the instrument referred to by Messrs. O'Neill and Thompson, in their note of the 7th August?

As stated therein, they constructed an instrument for me more than three years ago for the same purpose and on the same principle as that described by Dr. Woakes, but the invention dates back still further. I have yet in my possession a similar instrument that I roughly constructed myself in 1872, about the time the idea first occurred to me.

I do not accuse Dr. Woakes of having had any knowledge of my invention previous to his introducing his instrument to the profession—first, because there is no published account of mine, although one of them was exhibited in the Museum at the annual meeting of the British Medical Association in 1877; and, secondly, because I feel convinced his would have been divested of some of its present imperfections had he previously had a glimpse at mine.

The woodcuts give a fair idea of the general appearance of

the instrument; and a brief description will at once show the identity of principle in both, and the advantages of the older arrangement.

As seen in the figures, it is a dressing, or scissors-shaped, forceps I have used; and I think it will be at once admitted

that this form gives the operator much more command over the instrument than he could obtain with a spring forceps. The blades, A and B, Fig. 1, are slit up, so that each forms a needle-holder. The needle may be of any length, according to the part to be operated on, but has its eye near the centre, and has a small notch near its point. In Fig. 1, the instrument is seen ready for operation; on closing it, the notch in the needle allows the blade, B, to grasp it firmly, and on again disconnecting the handle the needle is released from A, or, in other words, it has passed from one blade to the other.

The advantages I claim for my instrument are:—First, the shape already adverted to; secondly, the needle is held in both blades by spring pressure, thereby obviating the necessity for a needle perforated or tubular at the base, which of course implies extra thickness; thirdly, by far the most important feature in my instrument is a very simple appliance to cause the tissue operated on to be well passed up on the needle before its point enters the catch on the opposite blade.

If Dr. Woakes has tried his instrument, I am sure he has not unfrequently found that a portion of the tissue is sometimes caught in the second blade of the forceps, as well as the needle; indeed, I have found it to obtain even where extra trouble was taken to have the needle thoroughly sharp.

To prevent such an unpleasant complication, I have introduced a sort of miniature blade between the other two, which somewhat resembles a flute key; as the instrument is closed the thumbscrew, D, impinges on the upper extremity of this blade, and tilts up the other extremity, which has a perforation sufficiently large to admit of the needle and thread passing freely through. Its action will be better understood by a reference to Fig. 2.

I am, Sir, faithfully yours,

N. FURLONG, M.R.I.A., &c.

Lymington, Enniscorthy, Sept. 7th, 1880.

** It is but justice to Mr. Furlong to state that a communication of similar purport to the above, but which was unfortunately mislaid, was received from him soon after the appearance in our columns of Dr. Woakes's paper.—ED. L.

HOSPITAL ETIQUETTE.

To the Editor of THE LANCET.

SIR,—On the 27th of May, 1880, a little boy was admitted into St. Mary's Hospital, Manchester, under Dr. Lloyd Roberts, suffering from stone in the bladder, and was transferred to me for operation. On the 2nd June symptoms of scarlet fever showed themselves. Information was at once sent to the Municipal Sanitary Authorities, by whose order the child was removed on the following day to the fever wards of the Children's Hospital at Pendlebury, the place appointed for the reception of those children suffering from infectious fevers who have to be accommodated at the public expense. When Dr. Mackenzie, the out-door medical officer at the Pendlebury Hospital, called at St. Mary's, to arrange for the boy's removal, he was informed by the house-surgeon, Dr. Walter, that upon his recovery he expected the boy to be returned to St. Mary's for operation; moreover, Dr. Walter called upon Dr. Ashby, the physician under whose care the boy was placed at Pendlebury, to tell him about the case, and to ask that it might be returned in due course. As a result of these interviews, Dr. Walter was satisfied that the boy would be returned, and so expressed himself to me. In order, however, that there might be no mistake, Dr. Lloyd Roberts made it his business on two separate occasions to see Dr. Ashby personally in reference to this matter, and he too received assurances that the patient would be sent back. You may judge of my surprise when I learnt last week that Mr. Thomas Jones (until the last few days surgeon to the Pendlebury Hospital) had operated on the boy a fortnight before, and of my indignation when I learnt that from the first the Pendlebury staff never meant the boy to return to St. Mary's—"at least not with the stone in his bladder."

Dr. Borchardt, the senior physician, admits, although informed of the request to have the case returned, that he said the case must be accepted without any restrictions, but adds that he was unaware that the child was sent in by order of the Corporation, otherwise he should have been returned. Dr. Borchardt, however, did not see that this decision was communicated to St. Mary's, neither did he take the trouble to ascertain through what channel the child was sent in, though it was not likely that a scarlet fever case from St. Mary's would come through any other source than the Corporation. I must own, too, that I cannot see how this question in any way affects the ethics of the case. Dr. Ashby admits, I believe, that he did not protest against Dr. Borchardt's decision, and certainly he did not inform Dr. Lloyd Roberts of it, but, on the contrary, gave him further assurance that the case would be returned, and now defends himself by saying that the operation was performed without his knowledge, during his absence of a week from Manchester, and before he calculated upon its being done.
